11 Outline

We let AG2 abbreviate the main paper “Identification- and Singularity-Robust Inference for Moment Condition Models.” References to sections with section numbers less than 11 refer to sections of AG2. All theorems, lemmas, and equations with section numbers less than 11 refer to results and equations in AG2.

We let SM abbreviate Supplemental Material. We let AG1 abbreviate the paper Andrews and Guggenberger (2017). The SM to AG1 is given in Andrews and Guggenberger (2014).

Section 12 provides further discussion of the literature related to AG2.

Section 13 extend the subvector tests in Section 9 to allow for the possibility that $\Omega_F = E_F g_i g_i'$ is singular.

Section 14 provides some miscellaneous backup material for AG2.

Section 15 introduces the SR-CQLR$_P$ test that applies when the moment functions are of a multiplicative form, $u_i(\theta) Z_i$, where $u_i(\theta)$ is a scalar residual and $Z_i$ is a $k$-vector of instrumental variables.

Sections 16 and 17 provide parts of the proofs of the asymptotic size results given in Sections 6 and 15.

Section 18 generalizes the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests from i.i.d. observations to strictly stationary strong mixing observations.

Section 19 compares the test statistics and conditioning statistics of the SR-CQLR, SR-CQLR$_P$, and Kleibergen’s (2005, 2007) CLR tests to those of Moreira’s (2003) LR statistic and conditioning statistic in the homoskedastic linear IV model with fixed (i.e., nonrandom) IV’s.

Section 20 provides finite-sample null rejection probability simulation results for the SR-AR and SR-CQLR tests for cases where the variance matrix of the moment functions is singular and near singular.

Section 21 provides finite-sample simulation results that illustrate that Kleibergen’s CLR test with moment-variance weighting can have low power in certain linear IV models with a single right-hand side (rhs) endogenous variable, as the theoretical results in Section 19 suggest.

Section 22 establishes some properties of the eigenvalue-adjustment procedure defined in Section 5.1 and used in the definitions of the SR-CQLR and SR-CQLR$_P$ tests.

Section 23 defines a new SR-LM test.

proves Theorem 18.1 which concerns the time series results. Section 31 proves Theorems 9.1, 13.1, and 9.2 which concern the subvector inference results.

For notational simplicity, throughout the SM, we often suppress the argument $\theta_0$ for various quantities that depend on the null value $\theta_0$.

12 Further Discussion of the Related Literature

Some asymptotic size results in the linear IV regression model with a single right-hand-side endogenous variable (i.e., $p = 1$) include the following. Mikusheva (2010) establishes the correct asymptotic size of LM and CLR tests in the linear IV model when the errors are homoskedastic. Guggenberger (2012) establishes the correct asymptotic size of heteroskedasticity-robust LM and CLR tests in a heteroskedastic linear IV model.

Subvector inference via the Bonferroni or Scheffé projection method, is discussed in see Cavanagh, Elliott, and Stock (1995), Chaudhuri, Richardson, Robins, and Zivot (2010), Chaudhuri and Zivot (2011), and McCloskey (2017) for Bonferroni’s method, and Dufour (1989) and Dufour and Jasiak (2001) for the projection method. Both methods are conservative, but Bonferroni’s method is found to work quite well by Chaudhuri, Richardson, Robins, and Zivot (2010) and Chaudhuri and Zivot (2011).\footnote{Cavanagh, Elliott, and Stock (1995) provide a refinement of Bonferroni’s method that is not conservative, but it is much more intensive computationally. McCloskey (2017) also considers a refinement of Bonferroni’s method.} Andrews (2017) provides subvector methods that are closely related to...
the Bonferroni method but are not conservative asymptotically.

Other results in the literature on subvector inference include the following. Subvector inference in which nuisance parameters are profiled out is possible in the linear IV regression model with homoskedastic errors using the AR test, but not the LM or CLR tests, see Guggenberger, Kleibergen, Mavroeidis, and Chen (2012). Andrews and Cheng (2012, 2013a,b) provide subvector tests with correct asymptotic size based on extremum estimator objective functions. These subvector methods depend on the following: (i) one has knowledge of the source of the potential lack of identification (i.e., which subvectors play the roles of $\beta$, $\pi$, and $\zeta$ in their notation), (ii) there is only one source of lack of identification, and (iii) the estimator objective function does not depend on the weakly identified parameters $\pi$ (in their notation) when $\beta = 0$, which rules out some weak IV’s models.\footnote{Montiel Olea (2012) also provides some subvector analysis in the extremum estimator context of Andrews and Cheng (2012). His efficient conditionally similar tests apply to the subvector $(\pi, \zeta)$ of $(\beta, \pi, \zeta)$ (in Andrews and Cheng’s (2012) notation), where $\beta$ is a parameter that determines the strength of identification and is known to be strongly identified. The scope of this subvector analysis is analogous to that of Stock and Wright (2000) and Kleibergen (2004).} Cheng (2015) provides subvector inference in a nonlinear regression model with multiple nonlinear regressors and, hence, multiple potential sources of lack of identification. I. Andrews and Mikusheva (2016) develop subvector inference methods in a minimum distance context based on Anderson-Rubin-type statistics. Cox (2017) provides subvector methods in a class of models that allows for multiple sources of weak identification and includes factor models. I. Andrews and Mikusheva (2015) provide conditions under which subvector inference is possible in exponential family models (but the requisite conditions seem to be quite restrictive). I. Andrews (2018) considers subvector inference in the context of a two-step procedure that determines first whether one should use an identification-robust method or not.

Phillips (1989) and Choi and Phillips (1992) provide asymptotic and finite-sample results for estimators and classical tests in simultaneous equations models that may be unidentified or partially identified when $p \geq 1$. However, their results do not cover weak identification (of standard or nonstandard form) or identification-robust inference. Hillier (2009) provides exact finite-sample results for CLR tests in the linear model under the assumption of homoskedastic normal errors and known covariance matrix. Antoine and Renault (2009, 2010) consider GMM estimation under semi-strong and strong identification, but do not consider tests or CS’s that are robust to weak identification. Armstrong, Hong, and Nekipelov (2012) show that standard Wald tests for multiple restrictions in some nonlinear IV models can exhibit size distortions when some IV’s are strongly identified and others are semi-strongly identified—not weakly identified. These results indicate that identification issues can be more severe in nonlinear models than in linear models, which provides...
further motivation for the development of identification-robust tests for nonlinear models.

13 Subvector SR Tests for Potentially Singular Moments Variance Matrices

Figure SM-1 provides additional power comparisons to those given in Section 9.4 for the subvector null hypothesis in the endogenous probit model. Figure SM-1 provides results for \( \rho = 0 \), whereas Figure 1 in Section 9.4 provides results for \( \rho = .9 \). See Section 9.4 for a discussion of the results.

In the remainder of this section, we extend the subvector tests in Section 9 to allow for the possibility that \( \Omega_F = E_F g_i g_i' \) is singular. We employ the definitions in (4.3) (4.4) with \( \eta \) in place of \( \theta \). That is, \( \tilde{\sigma}_n(\theta, \beta) := rk(\Omega_n(\theta, \beta)) \) and \( \Omega_n(\theta, \beta) := A_n^2(\theta, \beta)\tilde{\Pi}_n(\theta, \beta)A_n^\Omega(\theta, \beta)' \), where \( \tilde{\Pi}_n(\theta, \beta) \) is the \( k \times k \) diagonal matrix with the eigenvalues of \( \Omega_n(\theta, \beta) \) on the diagonal in nonincreasing order, and \( A_n^\Omega(\theta, \beta) \) is a \( k \times k \) orthogonal matrix of eigenvectors corresponding to the eigenvalues in \( \tilde{\Pi}_n(\theta, \beta) \). We partition \( A_n^\Omega(\theta, \beta) \) according to whether the corresponding eigenvalues are positive or zero: \( A_n^\Omega(\theta, \beta) = [\tilde{A}_n(\theta, \beta), A_n^{\perp}(\theta, \beta)] \), where \( \tilde{A}_n(\theta, \beta) \in \mathbb{R}^{k \times \tilde{\sigma}_n(\theta, \beta)} \) and \( A_n^{\perp}(\theta, \beta) \in \mathbb{R}^{k \times (k-\tilde{\sigma}_n(\theta, \beta))} \). The columns of \( \tilde{A}_n(\theta, \beta) \) are eigenvectors of \( \Omega_n(\theta, \beta) \) that correspond to positive eigenvalues of \( \tilde{\Omega}_n(\theta, \beta) \).

Analogously, consider the spectral decomposition for the population quantity, defined in (3.4) with \( \eta \) in place of \( \theta \), i.e., \( \Omega_F(\theta, \beta) = A_F^2(\theta, \beta)\Pi_F(\theta, \beta)A_F^\Omega(\theta, \beta)' \), and define \( r_F(\theta, \beta) := rk(\Omega_F(\theta, \beta)) \). We partition \( A_F^\Omega(\theta, \beta) \) as

\[
A_F^\Omega(\theta, \beta) = [A_F(\theta, \beta), A_F^{\perp}(\theta, \beta)], \quad \text{where} \quad A_F(\theta, \beta) \in \mathbb{R}^{k \times r_F(\theta, \beta)}, \quad A_F^{\perp}(\theta, \beta) \in \mathbb{R}^{k \times (k-r_F(\theta, \beta))}, \tag{13.1}
\]

and the columns of \( A_F(\theta, \beta) \) are eigenvectors of \( \Omega_F(\theta, \beta) \) that correspond to positive eigenvalues of \( \Omega_F(\theta, \beta) \). Let \( \Pi_F(\theta, \beta) \) denote the upper left \( r_F(\theta, \beta) \times r_F(\theta, \beta) \) submatrix of \( \Pi_F(\theta, \beta) \). The matrix \( \Pi_F(\theta, \beta) \) is diagonal with the positive eigenvalues of \( \Omega_F(\theta, \beta) \) on its diagonal in nonincreasing order. As above, we sometimes leave out the argument \( \theta \) and denote by \( \tilde{\Omega}_n(\beta) \) the matrix \( \tilde{\Omega}_n(\theta_0, \beta) \) and similarly for other expressions.

Recall the definition following (9.6) of \( \tilde{\beta}_n \), the null-restricted first-stage GMM estimator. Analogously to the full vector SR test, the subvector SR test is defined using the nonredundant moment functions. That is, rather than using the moment function \( g_i(\theta, \beta) \), the test of the hypothesis in (9.2) is based on

\[
g_{\tilde{\beta}_i}(\theta, \beta) = \tilde{A}_n(\theta_0, \tilde{\beta}_n)g_i(\theta, \beta) \in \mathbb{R}^{\tilde{r}_n(\theta_0, \tilde{\beta}_n)}. \tag{13.2}
\]
From now on, whenever a subindex $\hat{A}$ appears on an object defined in Section 9.2, it means that it is defined as in Section 9.2 but resulting from a moment condition model defined in terms of the nonredundant moment conditions $g_{\hat{A}_i}(\theta, \beta)$. In particular,

$$
\hat{\Omega}_{\hat{A}_n}(\theta, \beta) := n^{-1} \sum_{i=1}^{n} g_{\hat{A}_i}(\theta, \beta) g_{\hat{A}_i}(\theta, \beta)' - \hat{g}_{\hat{A}_n}(\theta, \beta) \hat{g}_{\hat{A}_n}(\theta, \beta)' \in R^{\hat{r}_n(\theta_0, \beta_n) \times \hat{r}_n(\theta_0, \beta_n)},
$$

$$
\hat{g}_{\hat{A}_n}(\theta, \beta) := n^{-1} \sum_{i=1}^{n} g_{\hat{A}_i}(\theta, \beta), \text{ and}
$$

$$
\hat{\beta}_{\hat{A}_n} := \arg \min_{\beta \in B} ||\hat{\varphi}_{\hat{A}_n} \hat{\gamma}_{\hat{A}_n}(\theta_0, \beta)||^2,
$$

where $\hat{\varphi}_{\hat{A}_n} \in R^{\hat{r}_n(\theta_0, \beta_n) \times \hat{r}_n(\theta_0, \beta_n)}$ satisfies

$$
\hat{\varphi}_{\hat{A}_n} \hat{\gamma}_{\hat{A}_n} = \hat{\Omega}_{\hat{A}_n}^{-1}(\theta_0, \beta_n). \tag{13.4}
$$

The subvector SR-AR and SR-CQLR test statistics, denoted by $SR-AR^S_{\hat{n}}(\theta_0, \hat{\beta}_{\hat{A}_n})$ and $SR-QLR^S_{\hat{n}}(\theta_0, \hat{\beta}_{\hat{A}_n})$, respectively, are defined as the nonrobust tests are defined, but based on the moment functions $g_{\hat{A}_i}(\theta, \beta)$ in place of $g_i(\theta, \beta)$ and using the GMM estimator $\hat{\beta}_{\hat{A}_n}$ rather than $\hat{\beta}_n$ to estimate the nuisance parameter $\beta$. When $\hat{r}_n(\theta_0, \beta_n) > 0$, the subvector SR-AR test at nominal size $\alpha \in (0, 1)$ rejects if

$$
SR-AR^S_{\hat{n}}(\theta_0, \hat{\beta}_{\hat{A}_n}) > \chi^2_{\hat{r}_n(\theta_0, \beta_n), 1-\alpha}. \tag{13.5}
$$

The subvector SR-CQLR test at nominal size $\alpha \in (0, 1)$ rejects if

$$
SR-QLR^S_{\hat{n}}(\theta_0, \hat{\beta}_{\hat{A}_n}) > c_{\hat{r}_n(\theta_0, \beta_n), \rho}(n^{1/2} \hat{D}^*_{\hat{A}_n}(\theta_0, \hat{\beta}_{\hat{A}_n}), \hat{J}_{\hat{A}_n}(\theta_0, \hat{\beta}_{\hat{A}_n}), 1-\alpha). \tag{13.6}
$$

If $\hat{r}_n(\theta_0, \beta_n) = 0$, then $SR-AR^S_{\hat{n}}(\theta_0, \hat{\beta}_{\hat{A}_n})$ and $SR-QLR^S_{\hat{n}}(\theta_0, \hat{\beta}_{\hat{A}_n}) := 0$ and $\chi^2_{\hat{r}_n(\theta_0, \beta_n), 1-\alpha}$ and $c_{\hat{r}_n(\theta_0, \beta_n), \rho}(n^{1/2} \hat{D}^*_{\hat{A}_n}(\theta_0, \hat{\beta}_{\hat{A}_n}), \hat{J}_{\hat{A}_n}(\theta_0, \hat{\beta}_{\hat{A}_n}), 1-\alpha) := 0$ and the two tests do not reject $H_0$.

Next, we define the parameter spaces for the subvector SR-AR and SR-CQLR tests. We denote the column and null spaces of a matrix by $\text{col}(\cdot)$ and $N(\cdot)$, respectively. We impose the conditions in $\mathcal{F}_{AR,1}^S$ defined in (9.14) which guarantee consistency of the preliminary estimator $\hat{\beta}_n$. The parameter space $\mathcal{F}_{AR,2}^S$ defined in (9.15) is modified in four ways: (i) the condition $\lambda_{\min}(E_F g_i g_i') \geq \delta$ is dropped, (ii) the condition $E_F \sup_{\beta \in B(\beta^*, \zeta^*)} ||\Pi_{1F}^{-1/2}(\beta) A_F(\beta)'(g_i(\beta) - E_F g_i(\beta))||^2 \leq M$ is added, (iii) all of the remaining conditions are formulated in terms of the moment functions $\Pi_{1F}^{-1/2}(\theta_0, \beta^*) A_F(\theta_0, \beta^*) g_i(\theta_0, \beta)$, rather than $g_i(\theta_0, \beta)$, and (iv) the condition, for some $\zeta^*_+ > 0$, $N(\Omega_F(\theta_0, \beta^*)) = N(\Omega_F(\theta_0, \beta))$ for all $\beta \in B(\beta^*, \zeta^*_+)$, where $\beta^*$ denotes the true value of $\beta$, is added. Call the resulting space $\mathcal{F}_{AR,2}^{SSR}$. We define the null parameter space for the subvector SR
AR test to be
\[ F_{AR}^{S,SR} := F_{AR,1} \cap F_{AR,2} . \]  

(13.7)

The null parameter space for the subvector SR-CQLR test, denoted by \( F_{AR}^{S,SR} \), is defined as \( F_{AR}^{S} \) is defined in (9.17) with the following modifications. First, \( F_{AR}^{S} \) is replaced by \( F_{AR}^{S,SR} \), and second, all of the remaining conditions are formulated in terms of the moment functions \( \Pi_{1F}^{-1/2}(\theta_0, \beta^*) A_F(\theta_0, \beta^*)' \times g_i(\theta_0, \beta) \), rather than \( g_i(\theta_0, \beta) \).

We can also construct confidence regions for \( \theta \) with correct asymptotic confidence size by inversion of the subvector SR-AR and SR-CQLR tests. The relevant parameter spaces are given by

\[ F_{\Theta,AR}^{S,SR} := \{ (F, \beta, \theta_0) : (F, \beta) \in F_{AR}^{S,SR}(\theta_0), \theta_0 \in \Theta \} \]  
\[ F_{\Theta}^{S,SR} := \{ (F, \beta, \theta_0) : (F, \beta) \in F_{S,SR}(\theta_0), \theta_0 \in \Theta \}, \]  

(13.8)

respectively, where \( F_{AR}^{S,SR}(\theta_0) \) and \( F_{S,SR}(\theta_0) \) denote \( F_{AR}^{S,SR} \) and \( F_{S,SR} \) with the latter set's dependence on \( \theta_0 \) made explicit.

Note that condition (iv) of \( F_{AR}^{S,SR} \) can be restrictive. We now discuss a scenario in which it holds. Consider the case where the moment functions are of the form

\[ g_i(\theta, \beta) = u_i(\theta, \beta) Z_i, \]  
(13.9)

where \( Z_i \) is a vector of instrument variables, the residual \( u_i(\theta, \beta) \) is scalar, \( E_F u_i^2(\theta_0, \beta^*) > 0 \), and \( E_F u_i^2(\theta_0, \beta^*) Z_i Z_i' \) factors into \( E_F u_i^2(\theta_0, \beta^*) E_F Z_i Z_i' \). (Note that the latter condition is implied by conditional homoskedasticity: \( E_F (u_i^2(\theta_0, \beta^*)|Z_i) = \sigma^2 \) a.s. for some constant \( \sigma^2 > 0 \).) Under these conditions, \( \Omega_F(\theta_0, \beta) = E_F u_i^2(\theta_0, \beta) Z_i Z_i' - E_F u_i(\theta_0, \beta) Z_i E_F u_i(\theta_0, \beta) Z_i' \) and \( \Omega_F(\theta_0, \beta^*) = E_F u_i^2(\theta_0, \beta^*) E_F Z_i Z_i' \). If \( A_F \Pi_F A_F' \) denotes a singular value decomposition of \( E_F Z_i Z_i' \) with \( \Pi_F = Diag(\Pi_{1F}, \Pi_{0F}) \), where \( \Pi_{1F} \) is the nonzero eigenvalues and \( \Pi_{0F} \) is the zero eigenvalues and \( A_F = (A_{1F}, A_{0F}) \) is a decomposition of the matrix of eigenvectors corresponding to the nonzero/zero eigenvalues, respectively, then \( A_{0F} = N(\Omega_F(\theta_0, \beta^*)) \). It follows that \( A_F' E_F Z_i Z_i' A_F = Diag(\Pi_{1F}, \Pi_{0F}) \) and thus, in particular, \( E_F (A_F' Z_i)_{j}^2 = 0 \) for \( j = r+1, \ldots, k \). Therefore, \( (A_F' Z_i)_{j} = 0 \) a.s. for \( j = r+1, \ldots, k \). But then \( A_F' \Omega_F(\theta_0, \beta) A_F = E_F u_i^2(\theta_0, \beta) A_F' Z_i Z_i' A_F - E_F u_i(\theta_0, \beta) A_F' Z_i \cdot E_F u_i(\theta_0, \beta) Z_i' A_F \), for any \( \beta \in B \), equals a block diagonal matrix with lower right block equal to \( 0^{(k-r)\times(k-r)} \). This implies \( \Omega_F(\theta_0, \beta) A_{0F} = 0^{k\times(k-r)}, \text{ which implies that } N(\Omega_F(\theta_0, \beta^*)) \subset N(\Omega_F(\theta_0, \beta)). \) Thus, in the setup of (13.9), condition (iv) of \( F_{AR,2}^{S,SR} \) holds provided \( N(\Omega_F(\theta_0, \beta^*)) \) is not a strict subset of \( N(\Omega_F(\theta_0, \beta)) \).
Note that condition (iv) of $F_{S;SR}^{AR,2}$ implies that $r_F(\beta)$ is constant for all $\beta \in B(\beta^*, \zeta_1)$. Furthermore, it implies that $\text{col}(\Omega_F(\theta_0, \beta^*)) = \text{col}(\Omega_F(\theta_0, \beta))$ for all $\beta \in B(\beta^*, \zeta_1)$, i.e., that $\text{col}(A_F(\beta^*)) = \text{col}(A_F(\beta))$ for all $\beta \in B(\beta^*, \zeta_1)$. Therefore, without loss of generality, under condition (iv) of $F_{S;SR}^{AR,2}$, we can take $A_F(\beta) = A_F(\beta^*)$ for all $\beta \in B(\beta^*, \zeta_1)$, i.e., $A_F(\beta)$ does not depend on $\beta$ for all $\beta \in B(\beta^*, \zeta_1)$.

The asymptotic size and similarity results for the subvector SR-AR and SR-CQLR tests are as follows.

**Theorem 13.1** Suppose Assumption $gB$ holds. The asymptotic sizes of the subvector SR-AR and SR-CQLR tests defined in (13.5) and (13.6), respectively, equal their nominal size $\alpha \in (0, 1)$ for the null parameter spaces $F_{S;SR}^{AR}$ and $F_{S;SR}$, respectively. These tests are asymptotically similar (in a uniform sense) for the subsets of these parameter spaces that exclude distributions $F$ under which $g_1 = 0^k$ a.s. Analogous results hold for the corresponding subvector SR-AR and SR-CQLR CS's for the parameter spaces $F_{S;SR}^{AR}$ and $F_{S;SR}$.

**Comment:** Theorem 13.1 is proved in Section 31 below.

### 14 Miscellanei

#### 14.1 Moore-Penrose Expression for the SR-AR Statistic

The expression for the SR-AR statistic given in (4.8) of AG2 holds by the following calculations. For notational simplicity, we suppress the dependence of quantities on $\theta$. We have

\[
SR-AR_n = n\tilde{g}_n^t \hat{A}_n (\hat{A}_n^t \hat{\Omega}_n \hat{A}_n)^{-1} \hat{A}_n^t \tilde{g}_n = n\tilde{g}_n^t \hat{A}_n (\hat{A}_n^t \hat{\Omega}_n \hat{A}_n)^{-1} \hat{A}_n^t \tilde{g}_n = n\tilde{g}_n^t \hat{A}_n \hat{\Pi}_1 \hat{A}_n^t \tilde{g}_n \text{ and }
\]

\[
n\tilde{g}_n^t \hat{\Omega}_n^+ \tilde{g}_n = n\tilde{g}_n^t \hat{A}_n \hat{\Pi}_1 \hat{A}_n^t \tilde{g}_n = n\tilde{g}_n^t \hat{A}_n \hat{\Pi}_1 \hat{A}_n^t \tilde{g}_n = n\tilde{g}_n^t \hat{A}_n \hat{\Pi}_1 \hat{A}_n^t \tilde{g}_n \quad \text{(14.1)}
\]

where the spectral decomposition of $\hat{\Omega}_n$ given in (4.3) and (4.4) is used once in each equation above. It is not the case that $SR-AR_n(\theta)$ equals the rhs expression in (4.8) with probability one when $\hat{\Omega}_n^+ (\theta)$ is replaced by an arbitrary generalized inverse of $\hat{\Omega}_n (\theta)$.

The expression for the SR-AR statistic given in (4.6) is preferable to the Moore-Penrose expression in (4.8) for the derivation of the asymptotic results for the SR-AR test.
14.2 Computation Implementation

The computation times given in Section 5.3 are for the model in Section 10 for the country Australia, although the choice of country has very little effect on the times. The computation times for the PI-CLC, MM1-SU, and MM2-SU tests depend greatly on the choice of implementation parameters. For the PI-CLC test, these include (i) the number of linear combination coefficients "a" considered in the search over [0, 1], which we take to be 100, (ii) the number of simulation repetitions used to determine the best choice of "a," which we take to be 2000, and (iii) the number of alternative parameter values considered in the search for the best "a," which we take to be 41 for \( p = 1 \). For the MM1-SU and MM2-SU tests, the implementation parameters include (i) the number of variables in the discretization of the maximization problem, which we take to be 1000, and (ii) the number of points used in the numerical approximations of the integrals \( h1 \) and \( h2 \) that appear in the definitions of these tests, which we take to be 1000. The run-times for the PI-CLC, MM1-SU, and MM2-SU tests exclude some items, such as a critical value look up table for the PI-CLC test, that only need to be computed once when carrying out multiple tests. The computations are done in GAUSS using the lmpt application to do the linear programming required by the MM1-SU and MM2-SU tests. Note that the computation time for the SR-CQLR test could be reduced by using a look up table for the data-dependent critical values, which depend on \( p \) singular values. This would be most useful when \( p = 2 \).

15 SR-CQLR\(_p\) Test

In this section, we define the SR-CQLR\(_p\) test, which is quite similar to the SR-CQLR test, but relies on \( g_i(\theta) \) having a product form. This form is

\[
g_i(\theta) = u_i(\theta)Z_i, \tag{15.1}
\]

where \( Z_i \) is a \( k \) vector of IV’s, \( u_i(\theta) \) is a scalar residual, and the (random) function \( u_i(\cdot) \) is known. This is the case considered in Stock and Wright (2000). It covers many GMM situations, but can be restrictive. For example, it rules out Hansen and Scheinkman’s (1995) moment conditions for continuous-time Markov processes, the moment conditions often used with dynamic panel models, e.g., see Ahn and Schmidt (1995), Arellano and Bover (1995), and Blundell and Bond (1995), and moment conditions of the form \( g_i(\theta) = u_i(\theta) \odot Z_i \), where \( u_i(\theta) \) is a vector.

The SR-CQLR\(_p\) test reduces asymptotically to Moreira’s (2003) CLR test in the homoskedastic linear IV regression model with fixed IV’s for sequences of distributions in all identification
categories. In contrast, the SR-CQLR test does so only under sequences in the standard weak, semi-strong, and strong identification categories, see Section 6.2 for the definitions of these identification categories.

15.1 SR-CQLRₚ Parameter Space

When (15.1) holds, we define

\[ u_{\theta i}(\theta) := \frac{\partial}{\partial \theta} u_i(\theta) \in \mathbb{R}^p \quad \text{and} \quad u_i^*(\theta) := \left( \begin{array}{c} u_i(\theta) \\ u_{\theta i}(\theta) \end{array} \right) \in \mathbb{R}^{p+1}, \]

and we have \( G_i(\theta) = Z_i u_{\theta i}(\theta) \).

[30]

The null parameter space for the SR-CQLRₚ test is

\[
\mathcal{F}_{SR}^{\text{SR}} := \{ F \in \mathcal{F}^{SR} : E_F \left| \Pi_{1F}^{1/2} A_F' Z_i \right| |^{4+\gamma} \leq M, \ E_F \left| u_i^* \right|^{2+\gamma} \leq M, \text{ and} \\
E_F \left| \Pi_{1F}^{-1/2} A_F' Z_i \right|^2 u_i^2 1(u_i^2 > c) \leq 1/2 \}.
\]

(15.3)

for some \( \gamma > 0 \) and some \( M, c < \infty \), where \( \Pi_{1F} \) and \( A_F \) are defined in Section 3.2. By definition, \( \mathcal{F}_{SR}^{\text{SR}} \subset \mathcal{F}_{AR}^{\text{SR}} \).

The conditions in \( \mathcal{F}_{SR}^{\text{SR}} \) are only marginally stronger than those in \( \mathcal{F}^{SR} \), defined in (3.6). A sufficient condition for the last condition in \( \mathcal{F}_{SR}^{\text{SR}} \) to hold for some \( c < \infty \) is \( E_F u_i^4 \leq M \) for some sufficiently large \( M < \infty \) (using the first condition in \( \mathcal{F}_{SR}^{\text{SR}} \) and the Cauchy-Bunyakovsky-Schwarz inequality).

The conditions in \( \mathcal{F}_{SR}^{\text{SR}} \) place no restrictions on the column rank or singular values of \( E_F G_i \). The conditions in \( \mathcal{F}_{SR}^{\text{SR}} \) also place no restrictions on the variance matrix \( \Omega_F := E_F g_i g_i' \) of \( g_i \), such as \( \lambda_{\min}(\Omega_F) \geq \delta \) for some \( \delta > 0 \) or \( \lambda_{\min}(\Omega_F) > 0 \). Hence, \( \Omega_F \) can be singular.

In Section 3.2 it is noted that identification failure yields singularity of \( \Omega_F \) in likelihood scenarios. It also does so in all quasi-likelihood scenarios when the quasi-likelihood does not depend on some element(s) of \( \theta \) (or some transformation(s) of \( \theta \)) for \( \theta \) in a neighborhood of \( \theta_0 \). Another example where \( \Omega_F \) may be singular is the following homoskedastic linear IV model: \( y_{1i} = Y_{2i} \beta + U_i \) and \( Y_{2i} = Z_i' \pi + V_{2i} \), where all quantities are scalars except \( Z_i, \pi \in \mathbb{R}^{d_X} \) and \( \theta = (\beta, \pi')' \in \mathbb{R}^{1+d_X} \).

\[ ^{30} \text{As with } G(W_i, \theta) \text{ defined in (3.2), } u_{\theta i}(\theta) \text{ need not be a vector of partial derivatives of } u_i(\theta) \text{ for all sample realizations of the observations. It could be the vector of partial derivatives of } u_i(\theta) \text{ almost surely, rather than for all } W_i, \text{ which allows } u_{\theta i}(\theta) \text{ to have kinks, or a vector of finite differences of } u_i(\theta). \text{ For the asymptotic size results for the SR-CQLR}_{2} \text{ test given below to hold, } u_{\theta i}(\theta) \text{ can be any random } p \text{ vector that satisfies the conditions in } \mathcal{F}_{SR}^{\text{SR}} \text{ (defined in (15.3)).}
\]

\[ ^{31} \text{In this case, the moment functions equal the quasi-score and some element(s) or linear combination(s) of elements of moment functions, equal zero a.s. at } \theta_0 \text{ (because the quasi-score is of the form } g_i(\theta) = (\partial/\partial \theta) \log f(W_i, \theta) \text{ for some density or conditional density } f(W_i, \theta). \text{ This yields singularity of the variance matrix of the moment functions and of the expected Jacobian of the moment functions.}
\]
The corresponding reduced-form equations are \( y_{1i} = Z_i' \pi + V_{1i} \) and \( Y_{2i} = Z_i' \pi + V_{1i} \), where \( V_{1i} = U_i + V_{2i} \beta \). We assume \( E U_i = E V_{2i} = 0 \), \( E U_i Z_i = E V_{2i} Z_i = 0 \), and \( E (V_i V_i' | Z_i) = \Sigma_V \) a.s. for \( V_i := (V_{1i}, V_{2i})' \) and some \( 2 \times 2 \) constant matrix \( \Sigma_V \). The moment conditions for \( \theta \) are

\[
g_i(\theta) = ((y_{1i} - Z_i' \pi) Z_i', (Y_{2i} - Z_i' \pi) Z_i')' \in \mathbb{R}^k, \text{ where } k = 2d_Z.
\]

The variance matrix \( \Sigma_V \otimes EZ_i Z_i' \) of \( g_i(\theta_0) = (V_{1i} Z_i', V_{2i} Z_i')' \) is singular whenever the covariance between the reduced-form errors \( V_{1i} \) and \( V_{2i} \) is one (or minus one) or \( EZ_i Z_i' \) is singular. In this model, we are interested in joint inference concerning \( \beta \) and \( \pi \). This is of interest when one wants to see how the magnitude of \( \pi \) affects the range of plausible \( \beta \) values.

Section 3.2 and Grant (2013) note that \( \Omega_F \) can be singular in the model for interest rate dynamics in Jegannathan, Skoulakis, and Wang (2002, Sec. 6.2) (JSW). JSW consider five moment conditions and a four dimensional parameter \( \theta \). The first four moment functions in JSW are

\[
\begin{align*}
(a(b - r_i))_i^{-2\gamma} - \gamma \sigma^2 r_i^{-1},
(a(b - r_i))_i^{-2\gamma+1} - (\gamma - 1/2)\sigma^2, (b - r_i)_i^{-a} - (1/2)\sigma^2 r_i^{2\gamma-a-1},
(a(b - r_i))_i^{-\sigma} - (1/2)\sigma^3 r_i^{2\gamma-a-1},
\end{align*}
\]

where \( \theta = (a, b, \sigma, \gamma)' \) and \( r_i \) is the interest rate. The second and third functions are equivalent if \( \gamma = (a+1)/2 \); the second and fourth functions are equivalent if \( \gamma = (\sigma+1)/2 \); and the third and fourth functions are equivalent if \( \sigma = a \). Hence, the variance matrix of the moment functions is singular when one or more of these three restrictions on the parameters holds. When any two of these restrictions hold, the parameter also is unidentified.

Next, we specify the parameter space for \((F, \theta)\) that is used with the SR-CQLR\(_P\) CS. It is denoted by \( \mathcal{F}^{SR}_{P} \). For notational simplicity, the dependence of the parameter space \( \mathcal{F}^{SR}_{P} \) in (15.3) on \( \theta_0 \) is suppressed. When dealing with the SR-CQLR\(_P\) CS, rather than test, we make the dependence explicit and write it as \( \mathcal{F}^{SR}_{P}(\theta_0) \). We define

\[
\mathcal{F}^{SR}_{\theta, P} := \{(F, \theta_0) : F \in \mathcal{F}^{SR}_{P}(\theta_0), \theta_0 \in \Theta\}. \tag{15.4}
\]

### 15.2 Definition of the SR-CQLR\(_P\) Test

First, we define the CQLR\(_P\) test without the SR extension. It uses the statistics \( \hat{\gamma}_n(\theta), \hat{\Omega}_n(\theta), \) \( AR_n(\theta), \) and \( \hat{D}_n(\theta) \) (defined in (4.1), (4.2), and (5.2)). The CQLR\(_P\) test also uses analogues \( \hat{R}_n(\theta) \)
and \( \widehat{V}_n(\theta) \) of \( \widehat{R}_n(\theta) \) and \( \widehat{V}_n(\theta) \) (defined in (5.3)), respectively, which are defined as follows:

\[
\widehat{R}_n(\theta) := (B(\theta)' \otimes I_k) \widehat{V}_n(\theta) (B(\theta) \otimes I_k) \in \mathbb{R}^{(p+1)k \times (p+1)k},
\]

where

\[
\widehat{V}_n(\theta) := n^{-1} \sum_{i=1}^{n} \left( (u_i^* - \widehat{u}_n(\theta)) (u_i^* - \widehat{u}_n(\theta))' \right) \otimes (Z_i Z_i') \in \mathbb{R}^{(p+1)k \times (p+1)k},
\]

\[
\widehat{u}_n(\theta) := \frac{1}{Z} \sum_{i=1}^{n} Z_i \in \mathbb{R}^{p+1},
\]

\[
\tilde{\Sigma}_n(\theta) := (Z_n' Z_n)^{-1} Z_n' Z_n U^*(\theta) \in \mathbb{R}^{k \times (p+1)},
\]

\[
Z_{n \times k} := (Z_1, \ldots, Z_n)' \in R^{n \times k}, \quad U^*(\theta) := (u_1^*(\theta), \ldots, u_n^*(\theta))' \in R^{n \times (p+1)}, \quad \text{and}
\]

\[
B(\theta) := \begin{pmatrix} 1 & 0_p' \\ -\theta & -I_p \end{pmatrix} \in \mathbb{R}^{(p+1) \times (p+1)}, \tag{15.5}
\]

where \( u_i^* := (u_i(\theta), u_{\theta_i}(\theta))' \) is defined in (15.2). Note that (i) \( \widehat{V}_n(\theta) \) is an estimator of the variance matrix of the moment functions and their vectorized derivatives, (ii) \( \widehat{V}_n(\theta) \) exploits the functional form of the moment conditions given in (15.1), (iii) \( \widehat{V}_n(\theta) \) typically is not of a Kronecker product form (because of the average over \( i = 1, \ldots, n \)), and (iv) \( \widehat{u}_n(\theta) \) is the best linear predictor of \( u_i^*(\theta) \) based on \( \{Z_i : n \geq 1\} \). The estimators \( \widehat{R}_n(\theta) \), \( \tilde{\Sigma}_n(\theta) \), and \( \tilde{\Sigma}_n(\theta) \) (defined immediately below) are defined so that the SR-CQLR\(_P\) test, which employs them, is asymptotically equivalent to Moreira’s (2003) CLR test under all strengths of identification in the homoskedastic linear IV model with fixed IV’s and \( p \) rhs endogenous variables for any \( p \geq 1 \), see Section 19 for details. The SR-CQLR\(_P\) test differs from the SR-CQLR test because \( \widehat{V}_n(\theta) \) (and the statistics that depend on it) differs from \( \tilde{\Sigma}_n(\theta) \) (and the statistics that depend on it).

We define \( \tilde{\Sigma}_n(\theta) \in \mathbb{R}^{(p+1) \times (p+1)} \) just as \( \tilde{\Sigma}_n(\theta) \) is defined in (5.4) and (5.5), but with \( \widehat{R}_n(\theta) \) in place of \( \widehat{R}_n(\theta) \). We define \( \tilde{D}_n(\theta) \) just as \( \tilde{D}_n(\theta) \) is defined in (5.7), but with \( \tilde{\Sigma}_n(\theta) \) in place of \( \tilde{\Sigma}_n(\theta) \). That is,

\[
\tilde{D}_n(\theta) := \tilde{\Sigma}_n(\theta)^{-1/2} \tilde{D}_n(\theta) \tilde{L}_n^{1/2}(\theta) \in \mathbb{R}^{k \times p}, \quad \text{where} \quad \tilde{L}_n(\theta) := (\theta, I_p)(\tilde{\Sigma}_n(\theta)^{-1}(\theta, I_p)'). \tag{15.6}
\]

The estimator \( \tilde{\Sigma}_n(\theta) \) is an estimator of a matrix that could be singular or nearly singular in some cases. For example, in the homoskedastic linear IV model, see Section 19.1 below, \( \tilde{\Sigma}_n(\theta) \) is an estimator of the variance matrix \( \Sigma_V \) of the reduced-form errors when \( \theta \) is the true parameter, and \( \Sigma_V \) could be singular or nearly singular. In the definition of \( \tilde{L}_n(\theta) \) above, we use an eigenvalue-adjusted version of \( \tilde{\Sigma}_n(\theta) \), denoted by \( \tilde{\Sigma}_n(\theta) \), whose condition number (i.e., \( \lambda_{\text{max}}(\tilde{\Sigma}_n(\theta))/\lambda_{\text{min}}(\tilde{\Sigma}_n(\theta)) \)) is bounded above by construction. Based on the finite-sample simulations, we recommend using \( \varepsilon = .01 \).

The QLR\(_P\) statistic without the SR extension, denoted by \( \text{QLR}_{P_n}(\theta) \), is defined just as \( \text{QLR}_n(\theta) \)
is defined in (5.7), but with \( \tilde{D}_n^*(\theta) \) in place of \( \hat{D}_n^*(\theta) \). For \( \alpha \in (0,1) \), the nominal size \( \alpha \) CQLR\(_P\) test (without the SR extension) rejects \( H_0: \theta = \theta_0 \) if

\[
\text{QLR}_P(n_\theta) > c_{k,p}(n^{1/2} \tilde{D}_n^*(\theta_0), 1 - \alpha),
\]

where \( c_{k,p}(\cdot, 1 - \alpha) \) is defined in (5.8). The nominal size 100\((1 - \alpha)\)% CQLR\(_P\) CS is \( CS_{\text{CQLR}_P,n} := \{ \theta_0 \in \Theta : \text{QLR}_P(n_\theta) \leq c_{k,p}(n^{1/2} \tilde{D}_n^*(\theta_0), 1 - \alpha) \} \).

The CQLR\(_P\) test statistic and critical value satisfy the following invariance properties.

**Lemma 15.1** The statistics \( \text{QLR}_P(n_\theta), c_{k,p}(n^{1/2} \tilde{D}_n^*, 1 - \alpha), \tilde{D}_n^* \tilde{D}_n^*, A \tilde{D}_n, \tilde{u}_n^*, \tilde{\Sigma}_n, \) and \( \tilde{L}_n \) are invariant to the transformation \((Z_i, u_i^*) \sim (MZ_i, u_i^*) \) \( \forall i \leq n \) for any \( k \times k \) nonsingular matrix \( M \).

This transformation induces the following transformations: \( g_i \sim M g_i \) \( \forall i \leq n \), \( G_i \sim M G_i \) \( \forall i \leq n \), \( \tilde{g}_n \sim M \tilde{g}_n \), \( \tilde{G}_n \sim M \tilde{G}_n \), \( \tilde{\Sigma}_n \sim M \tilde{\Sigma}_n M' \), \( \tilde{\tilde{D}}_n \sim M^{-1} \tilde{\tilde{D}}_n \), \( \tilde{\tilde{V}}_n \sim (I_{p+1} \otimes M) \tilde{\tilde{V}}_n (I_{p+1} \otimes M') \), and \( \tilde{\tilde{R}}_n \sim (I_{p+1} \otimes M) \tilde{\tilde{R}}_n (I_{p+1} \otimes M') \).

**Comment:** This Lemma is important because it implies that one can obtain the correct asymptotic size of the CQLR\(_P\) test defined above without assuming that \( \lambda_{\text{min}}(\Omega_F) \) is bounded away from zero. It suffices that \( \Omega_F \) is nonsingular. The reason is that (in the proofs) one can transform the moments by \( g_i \sim M F g_i \), where \( M F \Omega_F M' = I_k \), such that the transformed moments have a variance matrix whose eigenvalues are bounded away from zero for some \( \delta > 0 \) (since \( \text{Var}_F(M F g_i) = I_k \)) even if the original moments \( g_i \) do not.

For the CQLR\(_P\) test with the SR extension, we define \( \hat{D}_n(\theta) := \hat{A}_n(\theta)' Z_i \in R^{n(\theta)} \) and \( Z_{An \times k}(\theta) := Z_{An \times k} \hat{A}_n(\theta) \in R^{n \times \tilde{r}_n(\theta)} \). We define

\[
\tilde{V}_n(\theta) := n^{-1} \sum_{i=1}^{n} \left( (u_i^* - \tilde{u}_{An}(\theta)) (u_i^* - \tilde{u}_{An}(\theta))' \right) \otimes (Z_{Ai}(\theta) Z_{Ai}(\theta)')
\]

\[
\in R^{(p+1)\tilde{r}_n(\theta) \times (p+1)\tilde{r}_n(\theta)},
\]

where

\[
\tilde{u}_{An}(\theta) := \tilde{\tilde{u}}_{An}(\theta)' Z_{Ai}(\theta) \in R^{p+1},
\]

\[
\tilde{\tilde{V}}_n(\theta) := (Z_{An \times k}(\theta)' Z_{An \times k}(\theta))^{-1} Z_{An \times k}(\theta)' U^*(\theta) \in R^{\tilde{r}_n(\theta) \times (p+1)},
\]

and \( \tilde{r}_n(\theta) \) and \( \tilde{A}_n(\theta) \) are defined in (4.3) and (4.4), respectively. In addition, we define \( \tilde{R}_n(\theta), \tilde{\Sigma}_{An}(\theta), \tilde{L}_n(\theta), \tilde{D}_n^*\tilde{D}_n^*, \) and \( \tilde{Q}_n(\theta) \) as \( \hat{R}_n(\theta), \hat{\Sigma}_{An}(\theta), \hat{L}_n(\theta), \hat{D}_n^*(\theta), \) and \( \hat{Q}_n(\theta) \) are defined, respectively, in (5.11) and (5.12), but with \( \tilde{V}_n(\theta) \) in place of \( \hat{V}_n(\theta) \) in the definition of \( \tilde{R}_n(\theta) \), with \( \tilde{R}_n(\theta) \) in place of \( \hat{R}_n(\theta) \) in the definition of \( \tilde{\Sigma}_{An}(\theta) \), and so on in the definitions of \( \tilde{L}_n(\theta), \tilde{D}_n^*(\theta), \) and \( \tilde{Q}_n(\theta) \). We define the test statistic \( \text{SR-QLR}_P(n_\theta) \) as \( \text{SR-QLR}_\alpha(n_\theta) \) is defined in (5.12), but with \( \tilde{\tilde{Q}}_{An}(\theta) \) in place of \( \hat{\tilde{Q}}_{An}(\theta) \).
Given these definitions, the nominal size $\alpha$ SR-CQLR$_P$ test rejects $H_0 : \theta = \theta_0$ if

$$SR\text{-}CQLR_{Pn}(\theta_0) = c_{\alpha}(\theta_0) - p(n^{1/2}D_{An}(\theta_0), 1 - \alpha) \text{ or } \hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) \neq 0^{k-\hat{r}_n(\theta_0)}$$

(15.9)

The nominal size 100$(1 - \alpha)^\%$ SR-CQLR$_P$ CS is $CS_{SR\text{-}CQLR_{Pn},n} := \{\theta_0 \in \Theta : SR\text{-}CQLR_{Pn}(\theta_0) \leq c_{\alpha}(\theta_0) - p(n^{1/2}D_{An}(\theta_0), 1 - \alpha) \text{ and } \hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) = 0^{k-\hat{r}_n(\theta_0)}\}$.

Two simple examples where the extra rejection condition in (15.9) for the SR-CQLR$_P$ test (and in (4.7) and (5.13) for the SR-AR and SR-CQLR tests, respectively) improves the power of these tests are the following. First, suppose $(X_{1i}, X_{2i})' \sim$ i.i.d. $N(\theta, \Omega_F)$, where $\theta = (\theta_1, \theta_2)' \in R^2$, $\Omega_F$ is a 2 $\times$ 2 matrix of ones, and the moment functions are $g_i(\theta) = (X_{1i} - \theta_1, X_{2i} - \theta_2)'$. In this case, $\Omega_F$ is singular, $\hat{A}_{n}(\theta_0) = (1,1)'$ a.s., $\hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) = (1,-1)'$ a.s., the SR-AR statistic is a quadratic form in $\hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) = X_{1n}+X_{2n}-(\theta_1+\theta_2)$, where $X_{mn} = n^{-1}\sum_{i=1}^n X_{mi}$ for $m = 1, 2$, and $\hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) = X_{1n}-X_{2n}-(\theta_1-\theta_2)$ a.s. If one does not use the extra rejection condition, then the SR-AR test has no power against alternatives $\theta = (\theta_1, \theta_2)' (\neq 0)$ for which $\theta_1 + \theta_2 = \theta_{10} + \theta_{20}$.

The same is true for the SR-CQLR and SR-CQLR$_P$ tests (because the SR-CQLR$_n$ and SR-CQLR$_{Pn}$ test statistics depend on the SR-AR$_n$ test statistic). However, when the extra rejection condition is utilized, all $\theta \in R^2$ except those on the line $\theta_1 - \theta_2 = \theta_{10} - \theta_{20}$ are rejected with probability one (because $X_{1n}-X_{2n} = EFX_{1i}-EFX_{2i} = \theta_1 - \theta_2$ a.s.) and this includes all of the alternative $\theta$ values for which $\theta_1 + \theta_2 = \theta_{10} + \theta_{20}$.

Second, suppose $X_i \sim$ i.i.d. $N(\theta_1, \theta_2)$, $\theta = (\theta_1, \theta_2)' \sim R^2$, the moment functions are $g_i(\theta) = (X_i - \theta_1, X_i^2 - \theta_1^2 - \theta_2)'$, and the null hypothesis is $H_0 : \theta = (\theta_{10}, \theta_{20})'$. Consider alternative parameters of the form $\theta = (\theta_1, 0)'$. Under $\theta$, $X_i$ has variance zero, $X_i = X_{in} = \theta_1$ a.s., $X_i^2 = X_{i\theta}^2 = \theta_1^2$ a.s., where $X_i := n^{-1}\sum_{i=1}^n X_i^2$, $\hat{g}_n(\theta_0) = (\theta_1 - \theta_{10}, \theta_1^2 - \theta_{10}^2 - \theta_{20})'$ a.s., $\hat{A}_{n}(\theta_0) = \hat{g}_n(\theta_0)^{\frac{1}{2}}\hat{g}_n(\theta_0)' - \hat{g}_n(\theta_0)\hat{g}_n(\theta_0)' = 0^{2 \times 2}$ a.s. (provided $\hat{A}_{n}(\theta_0)$ is defined as in (4.1) with the sample means subtracted off), and $\hat{r}_n(\theta_0) = 0$ a.s. In consequence, if one does not use the extra rejection condition, then the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests have no power against alternatives of the form $\theta = (\theta_1, 0)'$ (because, by definition, the test statistics and critical values equal zero when $\hat{r}_n(\theta_0) = 0$). However, when the extra rejection condition is utilized, all alternatives of the form

---

32 By definition, $\hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) \neq 0^{k-\hat{r}_n(\theta_0)}$ does not hold if $\hat{r}_n(\theta_0) = k$. If $\hat{r}_n(\theta_0) = 0$, then $SR\text{-}CQLR_{Pn}(\theta_0) := 0$ and $\chi_{\alpha}^2(\theta_0) = I_k$ and the SR-CQLR$_P$ test rejects $H_0$ if $\hat{g}_n(\theta_0) \neq 0^k$.

33 By definition, if $\hat{r}_n(\theta_0) = k$, the condition $\hat{A}_{n}(\theta_0)^{-\frac{1}{2}}\hat{g}_n(\theta_0) = 0^{k-\hat{r}_n(\theta_0)}$ holds.
\( \theta = (\theta_1, 0)' \) are rejected with probability one.34 35 36 37

When the sample variance matrix is singular, an alternative to using the \( \text{SR-AR}_n(\theta_0) \) statistic is to arbitrarily delete some moment conditions. However, this typically leads to different test results given the same data and can yield substantially different power properties of the test depending on which moment conditions are deleted, which is highly undesirable. The following simple example illustrates this. Suppose \( W_i = (W_{1i}, W_{2i}, W_{3i})' \) has a normal distribution with mean vector \((\theta_1, \theta_2, \theta_2)'\), all variances are equal to one, the covariance between \( W_{1i} \) and \( W_{2i} \) equals one, \((W_{1i}, W_{2i})\) and \( W_{3i} \) are independent, \( g(W_i, \theta) = (W_{1i} - \theta_1, W_{2i} - \theta_2, W_{3i} - \theta_2)' \), and the null hypothesis is \( H_0 : \theta = \theta_0 \) for some \( \theta_0 = (\theta_{01}, \theta_{02})' \in \mathbb{R}^2 \). The sample variance matrix is singular with probability one. A nonsingular sample variance matrix can be obtained by deleting the first moment condition or the second. If the first moment condition is deleted, the sample moments evaluated at \( \theta_0 \) are \((\overline{W}_{n2} - \theta_{02}, \overline{W}_{n3} - \theta_{02})' \). If the second moment condition is deleted, they are \((\overline{W}_{n1} - \theta_{01}, \overline{W}_{n3} - \theta_{02})' \). When \( \theta_1 - \theta_{10} \) and \( \theta_2 - \theta_{20} \) are not equal (where \( \theta_1 \) and \( \theta_2 \) denote the true values), these two sets of moment conditions are not the same. Furthermore, it is clear that the power of the two tests based on these two sets of moment conditions is quite different because the first set of sample moments contains no information about \( \theta_1 \), whereas the second set does.

34 This holds because the extra rejection condition in this case leads one to reject \( H_0 \) if \( \overline{X}_n \neq \theta_{10} \) or \( \overline{X}_n^2 - \theta_{10}^2 - \theta_{20} \neq 0 \), which is equivalent a.s. to rejecting if \( \theta_1 \neq \theta_{10} \) or \( \bar{\sigma}_1^2 - \theta_{10}^2 - \theta_{20} \neq 0 \) (because \( \overline{X}_n = \theta_1 \) a.s. and \( \overline{X}_n^2 = \theta_1^2 \) a.s. under \( \theta \)), which in turn is equivalent to rejecting if \( \theta_1 \neq \theta_{10} \) (because if \( \theta_{20} > 0 \) one or both of the two conditions is violated when \( \theta_1 \neq \theta_{10} \) and if \( \theta_{20} = 0 \), then \( \theta_1 \neq \theta_{10} \) only if \( \theta_1 \neq \theta_{10} \) since we are considering the case where \( \theta_2 = 0 \)).

35 In this second example, suppose the null hypothesis is \( H_0 : \theta = (\theta_{10}, 0)' \). That is, \( \theta_{20} = 0 \). Then, the SR-AR test rejects with probability zero under \( H_0 \) and the test is not asymptotically similar. This holds because \( \hat{g}_n(\theta_0) = (\overline{X}_n - \theta_{10}, \overline{X}_n^2 - \theta_{10}^2)' = (0, 0)' \) a.s., \( \hat{r}_n(\theta_0) = 0 \) a.s., \( \text{SR-AR}_n(\theta_0) = \chi^2_{\hat{r}_n(\theta_0), 1 - \alpha} = 0 \) a.s. (because \( \hat{r}_n(\theta_0) = 0 \) a.s.), and the extra rejection condition leads one to reject \( H_0 \) if \( \overline{X}_n \neq \theta_{10} \) or \( \overline{X}_n^2 - \theta_{10}^2 - \theta_{20} \neq 0 \), which is equivalent to \( \theta_{10} \neq \theta_{10} \) or \( \theta_{10}^2 - \theta_{10}^2 - \theta_{20} \neq 0 \) (because \( X_1 = \theta_1 \) a.s.), which holds with probability zero.

As shown in Theorem 6.1, the SR-AR test is asymptotically similar (in a uniform sense) if one excludes null distributions \( F \) for which the \( g_n(\theta_0) = 0 \) a.s. under \( F \), such as in the present example, from the parameter space of null distributions. But, the SR-AR test still has correct asymptotic size without such exclusions.

36 We thank Kirill Evdokimov for bringing these two examples to our attention.

37 An alternative definition of the SR-AR test is obtained by altering its definition given in Section 4 as follows. One omits the extra rejection condition given in (4.7), one defines the SR-AR statistic using a weight matrix that is nonsingular by construction when \( \tilde{\Omega}_n(\theta_0) \) is singular, and one determines the critical value by simulation of the appropriate quadratic form in mean zero normal variates when \( \tilde{\Omega}_n(\theta_0) \) is singular. For example, such a weight matrix can be constructed by adjusting the eigenvalues of \( \tilde{\Omega}_n(\theta_0) \) to be bounded away from zero, and using its inverse. However, this method has two drawbacks. First, it sacrifices power relative to the definition of the SR-AR test in (4.7). The reason is that it does not reject \( H_0 \) with probability one when a violation of the nonstochastic part of the moment conditions occurs. This can be seen in the example with identities in Section 4 and the two examples given here.

Second, it cannot be used with the SR-CQLR and SR-CQLR \(_2 \) tests introduced in Sections 6 and 15. The reason is that these tests rely on the statistic \( \hat{D}_n(\theta_0) \), defined in (5.2), that employs \( \Omega_n^{-1}(\theta_0) \) and if \( \Omega_n^{-1}(\theta_0) \) is replaced by a matrix that is nonsingular by construction, such as the eigenvalue-adjusted matrix suggested above, then one does not obtain asymptotic independence of \( g_n(\theta_0) \) and \( \hat{D}_n(\theta_0) \) after suitable normalization, which is needed to obtain the correct asymptotic size of the SR-CQLR and SR-CQLR\(_2 \) tests.
15.3 Asymptotic Size of the SR-CQLRₚ Test

The correct asymptotic size and similarity results for the SR-CQLRₚ test are as follows.

**Theorem 15.2** The asymptotic size of the SR-CQLRₚ test defined in (15.9) equals its nominal size \( \alpha \in (0,1) \) for the null parameter spaces \( \mathcal{F}^{SR}_p \). Furthermore, this test is asymptotically similar (in a uniform sense) for the subset of this parameter space that excludes distributions \( F \) under which \( g_i = 0^k \) a.s. Analogous results hold for the corresponding SR-CQLRₚ CS for the parameter space \( \mathcal{F}^{SR}_{\Delta_p} \), defined in (15.4).

**Comments:** (i) For distributions \( F \) under which \( g_i = 0^k \) a.s., the SR-CQLRₚ test rejects the null hypothesis with probability zero when the null is true. Hence, asymptotic similarity only holds when these distributions are excluded from the null parameter spaces.

(ii) The proof of Theorem 15.2 is given in Sections 16, 17, and 25-27 below.

15.4 Asymptotic Efficiency of the SR-CQLRₚ Test under Strong Identification

Here we show that the SR-CQLRₚ test is asymptotically efficient in a GMM sense under strong and semi-strong identification (when the variance matrix of the moments is nonsingular and the null parameter value is not on the boundary of the parameter space).

Suppose \( k \geq p \). Let \( A_F \) and \( \Pi_F \) be defined as in (3.4) and (3.5) and the paragraph following these equations with \( \theta = \theta_0 \). Define \( \lambda^*_F, \Lambda^*_F, \) and \( \{ \lambda^*_n, h : n \geq 1 \} \) as \( \lambda_F, \Lambda_{WU,F}, \) and \( \{ \lambda_n, h : n \geq 1 \} \), respectively, are defined in (16.16)-(16.18), but with \( g_i \) and \( G_i \) replaced by \( g^*_F i := \Pi_F^{-1/2} A_F g_i \) and \( G^*_F i := \Pi_F^{-1/2} A_F^* G_i \), with \( \mathcal{F} \) replaced by \( \mathcal{F}^{SR}_p \) in the definition of \( \mathcal{F}_{WU} \), and with \( W_F := W_1(W_2F) \) and \( U_F := U_1(U_2F) \) defined as in (16.11) with \( g_i \) and \( G_i \) replaced by \( g^*_Fi \) and \( G^*_Fi \). In addition, we restrict \( \{ \lambda^*_n, h : n \geq 1 \} \) to be a sequence for which \( \lambda_{\min}(E_{Fi}g_i g^*_i) > 0 \) for all \( n \geq 1 \). By definition, a sequence \( \{ \lambda^*_n, h : n \geq 1 \} \) is said to exhibit strong or semi-strong identification if \( n^{1/2}s^p_{Fi} \to \infty \), where \( s^p_{Fi} \) denotes the smallest singular value of \( E_F G^*_Fi \).

The \( LM_n \) and \( LM_n^{GMM} \) statistics are defined in (7.1). Let \( \chi^2_{p,1-\alpha} \) denote the \( 1-\alpha \) quantile of the \( \chi^2_p \) distribution. The critical value for the \( LM_n \) and \( LM_n^{GMM} \) tests is \( \chi^2_{p,1-\alpha} \).

**Theorem 15.3** Suppose \( k \geq p \). For any sequence \( \{ \lambda^*_n, h : n \geq 1 \} \) that exhibits strong or semi-strong identification (i.e., for which \( n^{1/2}s^p_{Fi} \to \infty \)) and for which \( \lambda^*_n, h \in \Lambda^*_F \) \( \forall n \geq 1 \), we have

\[ \text{The singular value } s^p_{Fi}, \text{ defined here, equals } s^p_{Fi}, \text{ defined in Section 6.2, for all } F \text{ with } \lambda_{\min}(\Omega_F) > 0, \text{ because in this case } \Omega_F = A_F \Pi_F A_F, \Omega^{-1/2}_F = A_F \Pi_F^{-1/2} A_F, \Omega^{-1/2}_F E_F G_i = A_F \Pi_F^{-1/2} A_F^* E_F G_i = A_F E_F G^*_F i, \text{ and } A_F \text{ is an orthogonal } k \times k \text{ matrix. Since we consider sequences here with } \lambda_{\min}(\Omega_{Fi}) = \lambda_{\min}(E_{Fi}g_i g^*_i) > 0 \text{ for all } n \geq 1, \text{ the definitions of strong and semi-strong identification used here and in Section 6.2 are equivalent.} \]
\[ (a) \ SR-QLR_{P_n} = QLR_{P_n} + o_p(1) = LM_n + o_p(1) = LM_n^{GMM} + o_p(1) \ and \\
(b) \ c_{k,p}(n^{1/2}D^*, 1 - \alpha) \rightarrow_p \chi^2_p, 1 - \alpha. \]

**Comments:** (i) Theorem \[15.3\] establishes the asymptotic efficiency (in a GMM sense) of the SR-CQLR\_P test under strong and semi-strong identification. Theorem \[15.3\] provides asymptotic equivalence results under the null hypothesis, but, by the definition of contiguity, these asymptotic equivalence results also hold under contiguous local alternatives.

(ii) The proof of Theorem \[15.3\] is given in Section \[28\].

### 15.5 Summary Comparison of CLR-type Tests in Kleibergen (2005) and AG2

We briefly summarize some of the results in AG1 and AG2 concerning Kleibergen’s (2005) moment-variance-weighted CLR (MVW-CLR) and Jacobian-variance-weighted CLR (JVW-CLR) tests, the SR-CQLR test in AG2, and the SR-CQLR\_P test introduced above. (i) The MVW-CLR test has correct asymptotic size for all \( p \geq 1 \) (for the parameter space in AG1, which imposes non-singularity of the variance matrix and some other conditions). (ii) The JVW-CLR test has correct asymptotic size for \( p = 1 \) (under similar conditions to the MVW-CLR test). (iii) For \( p \geq 2 \), AG1 provides an expression for the asymptotic size of the JWV-CLR test that depends on a vector of localization parameters. It is unknown whether the asymptotic size exceeds the nominal size. (iv) The MVW-CLR test is not asymptotically equivalent to Moreira’s (2003) CLR test in the homoskedastic linear IV (HLIV) model for any \( p \geq 1 \). (v) The JVW-CLR test is asymptotically equivalent to Moreira’s (2003) CLR test in the HLIV model for \( p = 1 \), but not for \( p \geq 2 \). (vi) The SR-CQLR test has correct asymptotic size for the parameter space \( F^{SR} \) in Section \[3.2\] which is larger than the parameter space in (i) and (ii). (vii) The SR-CQLR\_P test has correct asymptotic size for the parameter space \( F^{SR}_P \) (\( \subset F^{SR} \)). (viii) The SR-CQLR test is asymptotically equivalent to Moreira’s (2003) CLR test in the HLIV model for \( p = 1 \), but not for \( p \geq 2 \), although the difference for \( p = 2 \) is only due to the difference between treating the IV’s as random, rather than fixed. (ix) The SR-CQLR\_P test is asymptotically equivalent to Moreira’s (2003) CLR test in the HLIV model for all \( p \geq 1 \).

### 16 Tests without the Singularity-Robust Extension

The next two sections and Sections \[25\] \& \[27\] below are devoted to the proof of Theorems \[6.1\] and \[15.2\]. The proof proceeds in two steps. First, in this section, we establish the correct asymptotic size and asymptotic similarity of the tests and CS’s without the SR extension for parameter spaces of distributions that bound \( \lambda_{\min}(\Omega_F) \) away from zero. (These tests are defined in \[4.2\], \[5.9\], and
We provide parts of the proof of this result in this section and other parts in Sections 25-27 below. Second, we extend the proof to the case of the SR tests and CS’s. We provide the proof of this extension in Section 17 below.

16.1 Asymptotic Results for Tests without the SR Extension

For the AR, CQLR, and CQLR_P tests without the SR extension, we consider the following parameter spaces for the distribution \(F\) that generates the data under \(H_0 : \theta = \theta_0\):

\[
\mathcal{F}_{AR} := \{ F : E_{F} g_i = 0^k, E_{F}||g_i||^{2+\gamma} \leq M, \text{ and } \lambda_{\min}(E_{F}g_{i}g_{i}^\top) \geq \delta \},
\]

\[
\mathcal{F} := \{ F \in \mathcal{F}_{AR} : E_{F}||\text{vec}(G_i)||^{2+\gamma} \leq M \}, \text{ and }
\]

\[
\mathcal{F}_P := \{ F \in \mathcal{F} : E_{F}||Z_i||^{4+\gamma} \leq M, \ E_{F}||u_i^{*}||^{2+\gamma} \leq M, \ \lambda_{\min}(E_{F}Z_{i}Z_{i}^\top) \geq \delta \}
\]

(16.1)

for some \(\gamma, \delta > 0\) and \(M < \infty\). By definition, \(\mathcal{F}_P \subseteq \mathcal{F} \subseteq \mathcal{F}_{AR}\). The parameter spaces \(\mathcal{F}_{AR}, \mathcal{F},\) and \(\mathcal{F}_P\) are used for the AR, CQLR, and CQLR_P tests, respectively. For the corresponding CS’s, we use the parameter spaces: \(\mathcal{F}_{\Theta,AR} := \{ (F, \theta_0) : F \in \mathcal{F}_{AR}(\theta_0), \theta_0 \in \Theta \}, \mathcal{F}_\Theta := \{ (F, \theta_0) : F \in \mathcal{F}(\theta_0), \theta_0 \in \Theta \}, \text{ and } \mathcal{F}_{\Theta,P} := \{ (F, \theta_0) : F \in \mathcal{F}_P(\theta_0), \theta_0 \in \Theta \}, \)

where \(\mathcal{F}_{AR}(\theta_0), \mathcal{F}(\theta_0), \text{ and } \mathcal{F}_P(\theta_0)\) equal \(\mathcal{F}_{AR}, \mathcal{F},\) and \(\mathcal{F}_P\), respectively, with their dependence on \(\theta_0\) made explicit.

**Theorem 16.1** The AR, CQLR, and CQLR_P tests (without the SR extensions), defined in (4.2), (5.9), and (15.7), respectively, have asymptotic size equal to their nominal size \(\alpha \in (0,1)\) and are asymptotically similar (in a uniform sense) for the parameter spaces \(\mathcal{F}_{AR}, \mathcal{F},\) and \(\mathcal{F}_P\), respectively. Analogous results hold for the corresponding AR, CQLR, and CQLR_P CS’s for the parameter spaces \(\mathcal{F}_{\Theta,AR}, \mathcal{F}_\Theta,\) and \(\mathcal{F}_{\Theta,P}\), respectively.

**Comments:**

(i) The first step of the proof of Theorems 6.1 and 15.2 is to prove Theorem 16.1.

(ii) Theorem 16.1 holds for both \(k \geq p\) and \(k < p\). Both cases are needed in the proof of Theorems 6.1 and 15.2 (even if \(k \geq p\) in Theorems 6.1 and 15.2).

(iii) In Theorem 16.1 as in Theorems 6.1 and 15.2 we assume that the parameter space being considered is non-empty.

(iv) The results of Theorem 6.1 still hold if the moment bounds in \(\mathcal{F}_{AR}, \mathcal{F},\) and \(\mathcal{F}_P\) are weakened very slightly by, e.g., replacing \(E_{F}||g_i||^{2+\gamma} \leq M\) in \(\mathcal{F}_{AR}\) by \(E_{F}||g_i||^{2+\gamma}(||g_i|| > j) \leq \varepsilon_j\) for all integers \(j \geq 1\) for some \(\varepsilon_j > 0\) (that does not depend on \(F\)) for which \(\varepsilon_j \to 0\) as \(j \to \infty\). The latter conditions are weaker because, for any random variable \(X\) and constants \(\gamma, j > 0, EX^{2+\gamma}(X > j) \leq E|X|^{2+\gamma}/j^{\gamma}\). The latter conditions allow for the application of Lindeberg’s triangular array central limit theorem for independent random variables, e.g., see Billingsley (1979, 1986).
Thm. 27.2, p. 310), in scenarios where the distribution $F$ depends on $n$. For simplicity, we define the parameter spaces as is.

Analogously, the results in Theorems 6.1 and 15.2 still hold if the moment bounds in $\mathcal{F}_{AR}^S$, $\mathcal{F}_P^S$, and $\mathcal{F}_{AR}^R$ are weakened very slightly by, e.g., replacing $E_F\|\Pi_{1F}^{-1/2}A_{1F}^tg_i\|^2 + \gamma \leq M$ in $\mathcal{F}_{AR}^S$ by $E_F\|\Pi_{1F}^{-1/2}A_{1F}^tg_i\|^2(\|\Pi_{1F}^{-1/2}A_{1F}^tg_i\| > j) \leq \varepsilon_j$ for all integers $j \geq 1$ for some $\varepsilon_j > 0$ (that does not depend on $F$) for which $\varepsilon_j \to 0$ as $j \to \infty$.

The following lemma shows that the critical value function $c_{k,p}(D, 1 - \alpha)$ depends on $D$ only through its singular values.

**Lemma 16.2** Let $D$ be a $k \times p$ matrix with the singular value decomposition $D = CYB'$, where $C$ is a $k \times k$ orthogonal matrix of eigenvectors of $DD'$, $B$ is a $p \times p$ orthogonal matrix of eigenvectors of $D'D$, and $Y$ is the $k \times p$ matrix with the minimum singular values $\{\tau_j : j = \min\{k,p\}\}$ of $D$ as its first $\min\{k,p\}$ diagonal elements and zeros elsewhere, where $\tau_j$ is nonincreasing in $j$. Then, $c_{k,p}(D, 1 - \alpha) = c_{k,p}(Y, 1 - \alpha)$.

**Comment:** A consequence of Lemma 16.2 is that the critical value $c_{k,p}(n^{1/2}\hat{\Delta}_n^*(\theta_0), 1 - \alpha)$ of the CQLR test depends on $\hat{\Delta}_n^*(\theta_0)$ only through $\hat{\Delta}_n^*(\theta_0)'\hat{\Delta}_n^*(\theta_0)$ (because, when $k \geq p$, the $p$ singular values of $n^{1/2}\hat{\Delta}_n^*(\theta_0)$ equal the square roots of the eigenvalues of $n\hat{\Delta}_n^*(\theta_0)'\hat{\Delta}_n^*(\theta_0)$ and, when $k < p$, $c_{k,p}(D, 1 - \alpha)$ is the $1 - \alpha$ quantile of the $\chi_k^2$ distribution which does not depend on $D$).

### 16.2 Uniformity Framework

The proofs of Theorems 6.1, 15.2, and 16.1 use Corollary 2.1(c) in Andrews, Cheng, and Guggenberger (2019) (ACG), which provides general sufficient conditions for the correct asymptotic size and (uniform) asymptotic similarity of a sequence of tests.

Now we state Corollary 2.1(c) of ACG. Let $\{\phi_n : n \geq 1\}$ be a sequence of tests of some null hypothesis whose null distributions are indexed by a parameter $\lambda$ with parameter space $\Lambda$. Let $RP_n(\lambda)$ denote the null rejection probability of $\phi_n$ under $\lambda$. For a finite nonnegative integer $J$, let $\{h_n(\lambda) = (h_{1n}(\lambda), ..., h_{Jn}(\lambda))' \in R^J : n \geq 1\}$ be a sequence of functions on $\Lambda$. Define

$$H := \{h \in (R \cup \{-\infty\})^J : h_{wn}(\lambda_{wn}) \to h \text{ for some subsequence } \{w_n\}\}$$

of $\{n\}$ and some sequence $\{\lambda_{wn} \in \Lambda : n \geq 1\}$.  \hspace{1cm} (16.2)

**Assumption B**: For any subsequence $\{w_n\}$ of $\{n\}$ and any sequence $\{\lambda_{wn} \in \Lambda : n \geq 1\}$ for which $h_{wn}(\lambda_{wn}) \to h \in H$, $RP_{wn}(\lambda_{wn}) \to \alpha$ for some $\alpha \in (0,1)$.
Proposition 16.3 (ACG, Corollary 2.1(c)) Under Assumption B*, the tests \( \{ \phi_n : n \geq 1 \} \) have asymptotic size \( \alpha \) and are asymptotically similar (in a uniform sense). That is, \( \text{AsySz} := \limsup_{n \to \infty} \sup_{\lambda \in \Lambda} R_P(n, \lambda) = \alpha \) and \( \liminf_{n \to \infty} \inf_{\lambda \in \Lambda} R_P(n, \lambda) = \limsup_{n \to \infty} \sup_{\lambda \in \Lambda} R_P(n, \lambda) \).

Comments: (i) By Comment 4 to Theorem 2.1 of ACG, Proposition 16.3 provides asymptotic size and similarity results for nominal \( 1 - \alpha \) CS’s, rather than tests, by defining \( \alpha \) as one would for a test, but having it depend also on the parameter that is restricted by the null hypothesis, by enlarging the parameter space \( \Lambda \) correspondingly (so it includes all possible values of the parameter that is restricted by the null hypothesis), and by replacing (a) \( \phi_n \) by a CS based on a sample of size \( n \), (b) \( \alpha \) by \( 1 - \alpha \), (c) \( R_P(n, \lambda) \) by \( CP(n, \lambda) \), where \( CP(n, \lambda) \) denotes the coverage probability of the CS under \( \lambda \) when the sample size is \( n \), and (d) the first \( \limsup_{n \to \infty} \sup_{\lambda \in \Lambda} \) that appears by \( \liminf_{n \to \infty} \inf_{\lambda \in \Lambda} \). In the present case, where the null hypotheses are of the form \( H_0 : \theta = \theta_0 \) for some \( \theta_0 \in \Theta \), to establish the asymptotic size of CS’s, the parameter \( \theta_0 \) is taken to be a subvector of \( \lambda \) and \( \Lambda \) is specified so that the value of this subvector ranges over \( \Theta \).

(ii) In the application of Proposition 16.3 to prove Theorems 6.1, 15.2, and 16.1, one takes \( \alpha \) to be a one-to-one transformation of \( \mathcal{F}_{AR}, \mathcal{F}, \) or \( \mathcal{F}_P \) for tests, and one takes \( \lambda \) to be a one-to-one transformation of \( \mathcal{F}_{\theta,AR}, \mathcal{F}_{\theta}, \) or \( \mathcal{F}_{\theta,P} \) for CS’s. With these changes, the proofs for tests and CS’s are the same. In consequence, we provide explicit proofs for tests only and obtain the proofs for CS’s by analogous applications of Proposition 16.3.

(iii) We prove the test results in Theorems 16.1 and 15.2 using Proposition 16.3 by verifying Assumption B* for a suitable choice of \( \lambda, h_n(\lambda), \) and \( \Lambda \). The verification of Assumption B* is quite easy for the AR test. It is given in Section 27.6. The verifications of Assumption B* for the CQLR and CQLR_P tests are much more difficult. In the remainder of this Section 16, we provide some key results that are used in doing so. (These results are used only for the CQLR and CQLR_P tests, not the AR test.) The complete verifications for the CQLR and CQLR_P tests are given in Section 27.

16.3 General Weight Matrices \( \hat{W}_n \) and \( \hat{U}_n \)

As above, for notational simplicity, we suppress the dependence on \( \theta_0 \) of many quantities, such as \( g_i, G_i, u_{gi}, B, \) and \( f_i \), as well as the quantities \( V_F, R_F, \Xi_F, V_F, \) and \( R_F \), that are introduced below. To provide asymptotic results for the CQLR and CQLR_P tests simultaneously, we prove asymptotic results for a QLR test statistic and a conditioning statistic that depend on general random weight matrices \( \hat{W}_n \in R^{k \times k} \) and \( \hat{U}_n \in R^{p \times p} \). In particular, we consider statistics of the
form \( \hat{W}_n, \hat{D}_n, \hat{U}_n \) and functions of this statistic, where \( \hat{D}_n \) is defined in (5.2). Let

\[
QLR_{WU,n} := AR_n - \lambda_{\min}(nQ_{WU,n}),
\]

where

\[
\hat{Q}_{WU,n} := \left( \hat{W}_n \hat{D}_n \hat{U}_n, \hat{\Omega}_n^{-1/2} g_n \right) \left( \hat{W}_n \hat{D}_n \hat{U}_n, \hat{\Omega}_n^{-1/2} g_n \right)' \in R^{(p+1) \times (p+1)}.
\]

(16.3)

The definitions of the random weight matrices \( \hat{W}_n \) and \( \hat{U}_n \) depend upon the statistic that is of interest. They are taken to be of the form

\[
\hat{W}_n := W_1(\hat{W}_2n) \in R^{k \times k} \text{ and } \hat{U}_n := U_1(\hat{U}_2n) \in R^{p \times p},
\]

(16.4)

where \( \hat{W}_2n \) and \( \hat{U}_2n \) are random finite-dimensional quantities, such as matrices, and \( W_1(\cdot) \) and \( U_1(\cdot) \) are nonrandom functions that are assumed below to be continuous on certain sets. The estimators \( \hat{W}_2n \) and \( \hat{U}_2n \) have corresponding population quantities \( W_{2F} \) and \( U_{2F} \), respectively. Thus, the population quantities corresponding to \( \hat{W}_n \) and \( \hat{U}_n \) are

\[
W_F := W_1(W_{2F}) \text{ and } U_F := U_1(U_{2F}),
\]

(16.5)

respectively.

**Example 1:** For the CQLR test,

\[
\hat{W}_n := \hat{\Omega}_n^{-1/2} \text{ and } \hat{U}_n := \hat{L}_n^{1/2} := ((\theta_0, I_p)(\hat{\Sigma}_n^c)^{-1}(\theta_0, I_p)'\right)^{1/2},
\]

(16.6)

where \( \hat{\Omega}_n \) is defined in (4.1) and \( \hat{\Sigma}_n \) is defined in (5.4) and (5.5).

The population analogues of \( \hat{V}_n \) and \( \hat{R}_n \), defined in (5.3), are

\[
V_F := E_F(f_i - E_F f_i)(f_i - E_F f_i)' \in R^{(p+1)k \times (p+1)k} \text{ and }
\]

\[
R_F := (B' \otimes I_k)V_F (B \otimes I_k) \in R^{(p+1)k \times (p+1)k}.
\]

(16.7)

---

[^39]: The definition of \( \hat{Q}_{WU,n} \) in (16.3) writes the \( \lambda_{\min}(\cdot) \) quantity in terms of \( (\hat{W}_n \hat{D}_n \hat{U}_n, \hat{\Omega}_n^{-1/2} g_n) \), whereas (5.7) writes the \( \lambda_{\min}(\cdot) \) quantity in terms of \( (\hat{\Omega}_n^{-1/2} g_n, \hat{D}_n^*) \), which has the \( \hat{\Omega}_n^{-1/2} g_n \) vector as the first column rather than the last column. The ordering of the columns does not affect the value of the \( \lambda_{\min}(\cdot) \) quantity. We use the order \( (\hat{\Omega}_n^{-1/2} g_n, \hat{D}_n^*) \) in (5.7) because it is consistent with the order in Moreira (2003) and Andrews, Moreira, and Stock (2006, 2008). We use the order \( (\hat{W}_n \hat{D}_n \hat{U}_n, \hat{\Omega}_n^{-1/2} g_n) \) here because it has significant notational advantages in the proof of Theorem 16.6 below, which is given in Section 26.
In this case,

\[
\tilde{W}_{2n} := \hat{\Omega}_n, \quad W_{2F} := \Omega_F := E_F g_i g_i', \quad W_1(W_{2F}) := W_{2F}^{-1/2},
\]

\[
U_1(U_{2F}) := \left((\theta_0, I_p)(\Sigma^*(\Omega_F, R_F))^{-1}(\theta_0, I_p)\right)^{1/2},
\]

\[
\tilde{U}_{2n} := (\tilde{\Omega}_n, \tilde{R}_n), \quad U_{2F} := (\Omega_F, R_F), \quad \text{and}
\]

\[
\Sigma_{j\ell}(\Omega_F, R_F) = tr(R'_{j\ell F}\Omega_F^{-1})/k
\]  

(16.8)

for \( j, \ell = 1, \ldots, p + 1 \), where \( \Sigma_{j\ell}(\Omega_F, R_F) \in R^{(p+1)\times(p+1)} \) denotes the \((j, \ell)\) element \( \Sigma(\Omega_F, R_F) \), \( \Sigma(\Omega_F, R_F) \) is defined to minimize \( ||(I_{p+1} \otimes \Omega_F^{-1/2})[\Sigma \otimes \Omega_F - R_F](I_{p+1} \otimes \Omega_F^{-1/2})|| \) over symmetric positive definite matrices \( \Sigma \in R^{(p+1)\times(p+1)} \) (analogously to the definition of \( \tilde{\Sigma}_n \) in (5.4)), the last equality in (16.8) holds by the same argument as used to obtain (5.5), \( \Sigma^*(\Omega_F, R_F) \) is defined given \( \Sigma(\Omega_F, R_F) \) by (5.6), and \( R_{j\ell F} \) denotes the \((j, \ell)\) \( k \times k \) submatrix of \( R_F \).

**Example 2:** For the CQLR\(_P\) test, one takes \( \tilde{W}_{n}, \tilde{W}_{2n}, W_{2F}, W_1(\cdot), \) and \( U_1(\cdot) \) as in Example 1 and

\[
\tilde{U}_n := \tilde{L}^{1/2}_n := ((\theta_0, I_p)(\tilde{\Sigma}_n)^{-1}(\theta_0, I_p))^{1/2},
\]

(16.9)

where \( \tilde{\Sigma}_n = \tilde{\Sigma}_n(\theta_0) \) is defined just above (15.5) and \( \tilde{\Sigma}_n^* \) is defined given \( \tilde{\Sigma}_n \) by (5.6).

The population analogues of \( \tilde{V}_n \) and \( \tilde{R}_n \), defined in (15.5), are

\[
\tilde{V}_F := E_F f_i f'_i - E_F((g_i, G_i)'Z_i Z'_i) - E_F(\Xi_F (g_i, G_i) \otimes Z_i Z'_i) \\
+ E_F(\Xi'_F Z_i Z'_i \Xi_F \otimes Z_i Z'_i) \in R^{(p+1)k \times (p+1)k}
\]

and

\[
\tilde{R}_F := (B' \otimes I_k)\tilde{V}_F(B \otimes I_k) \in R^{(p+1)k \times (p+1)k},
\]

(16.10)

where

\[
\Xi_F := (E_F Z_i Z'_i)^{-1} E_F (g_i, G_i) \in R^{k \times (p+1)},
\]

\( f_i := (g'_i, vec(G'_i))' \in R^{(p+1)k} \),

and \( B = B(\theta_0) \) is defined in (5.3).

For the CQLR\(_P\) test,

\[
\tilde{U}_{2n} := (\tilde{\Omega}_n, \tilde{R}_n), \quad U_{2F} := (\Omega_F, \tilde{R}_F), \quad \text{and}
\]

\[
\Sigma_{j\ell}(\Omega_F, \tilde{R}_F) = tr(R'_{j\ell F}\Omega_F^{-1})/k,
\]

(16.11)

for \( j, \ell = 1, \ldots, p + 1 \), where \( \Sigma_{j\ell}(\Omega_F, \tilde{R}_F) \in R^{(p+1)\times(p+1)} \) denotes the \((j, \ell)\) element \( \Sigma(\Omega_F, \tilde{R}_F) \), \( \Sigma(\Omega_F, \tilde{R}_F) \) is defined to minimize \( ||(I_{p+1} \otimes \Omega_F^{-1/2})[\Sigma \otimes \Omega_F - \tilde{R}_F](I_{p+1} \otimes \Omega_F^{-1/2})|| \) over symmetric positive definite matrices \( \Sigma \in R^{(p+1)\times(p+1)} \) (analogously to the definition of \( \tilde{\Sigma}_n(\theta) \) in (5.4)), the last equality in

\[\text{Note that } W_1(W_{2F}) \text{ and } U_1(U_{2F}) \text{ in (16.8) define the functions } W_1(\cdot) \text{ and } U_1(\cdot) \text{ for any conformable arguments, such as } \tilde{W}_{2n} \text{ and } \tilde{U}_{2n}, \text{ not just for } W_{2F} \text{ and } U_{2F}.\]
(16.11) holds by the same argument as used to obtain (5.5), \( \Sigma^e(\Omega_F, \tilde{R}_F) \) is defined given \( \Sigma(\Omega_F, \tilde{R}_F) \) by (5.6), and \( \tilde{R}_{j\ell F} \) denotes the \((j, \ell)\) submatrix of \( \tilde{R}_F \).

We provide results for distributions \( F \) in the following set of null distributions:

\[
\mathcal{F}_{WU} := \{ F \in \mathcal{F} : \lambda_{\min}(W_F) \geq \delta_1, \lambda_{\min}(U_F) \geq \delta_1, ||W_F|| \leq M_1, \text{ and } ||U_F|| \leq M_1 \} \tag{16.12}
\]

for some constants \( \delta_1 > 0 \) and \( M_1 < \infty \), where \( \mathcal{F} \) is defined in (16.1).

For the CQLR test, which uses the definitions in (16.6)-(16.8), we show that \( \mathcal{F} \subset \mathcal{F}_{WU} \) for \( \delta_1 > 0 \) sufficiently small and \( M_1 < \infty \) sufficiently large, see Lemma 27.4(a). Hence, uniform results over \( \mathcal{F}_{WU} \) for this test imply uniform results over \( \mathcal{F} \).

For the CQLR\(_P\) test, which uses the definitions in (16.9)-(16.11), we show that \( \mathcal{F}_{P} \subset \mathcal{F}_{WU} \) for \( \delta_1 > 0 \) sufficiently small and \( M_1 < \infty \) sufficiently large, where \( \mathcal{F} \) is defined in (16.1), see Lemma 27.4(b) in Section 27.1. Hence, uniform results over \( \mathcal{F}_{P} \cap \mathcal{F}_{WU} \) for arbitrary \( \delta_1 > 0 \) and \( M_1 < \infty \) for this test imply uniform results over \( \mathcal{F}_{P} \).

### 16.4 Uniformity Reparametrization

To apply Proposition 16.3, we reparametrize the null distribution \( F \) to a vector \( \lambda \). The vector \( \lambda \) is chosen such that for a subvector of \( \lambda \) convergence of a drifting subsequence of the subvector (after suitable renormalization) yields convergence in distribution of the test statistic and convergence in distribution of the critical value in the case of the CQLR tests. In this section, we define \( \lambda \) for the CQLR and CQLR\(_P\) tests. The same definition is used for both tests. The (much simpler) definition of \( \lambda \) for the AR test is given in Section 27.6 below.

The vector \( \lambda \) depends on the following quantities. Let

\[
B_F \text{ denote a } p \times p \text{ orthogonal matrix of eigenvectors of } U'_F(E_F G_i)' W'_F W_F (E_F G_i) U_F \tag{16.13}
\]

ordered so that the corresponding eigenvalues \( (\kappa_{1F}, \ldots, \kappa_{pF}) \) are nonincreasing. The matrix \( B_F \) is such that the columns of \( W_F (E_F G_i) U_F B_F \) are orthogonal. Let

\[
C_F \text{ denote a } k \times k \text{ orthogonal matrix of eigenvectors of } W_F (E_F G_i) U_F U'_F (E_F G_i)' W'_F \tag{16.14}
\]

\[\text{The matrices } B_F \text{ and } C_F \text{ are not uniquely defined. We let } B_F \text{ denote one choice of the matrix of eigenvectors of } U'_F (E_F G_i)' W'_F W_F (E_F G_i) U_F \text{ and analogously for } C_F.\]
The corresponding eigenvalues are \((\kappa_1 F, ..., \kappa_k F) \in R^k\). Let

\[
(\tau_1 F, ..., \tau_{\min\{k,p\} F}) \text{ denote the } \min\{k,p\} \text{ singular values of } W_F(E_F G_i) U_F, \tag{16.15}
\]

which are nonnegative, ordered so that \(\tau_j F\) is nonincreasing. (Some of these singular values may be zero.) As is well-known, the squares of the \(\min\{k,p\}\) singular values of a \(k \times p\) matrix \(A\) equal the \(\min\{k,p\}\) largest eigenvalues of \(A' A\) and \(AA'\). In consequence, \(\kappa_j F = \tau_{j F}^2\) for \(j = 1, ..., \min\{k,p\}\). In addition, \(\kappa_j F = 0\) for \(j = \min\{k,p\} + 1, ..., \max\{k,p\}\).

Define the elements of \(\lambda\) to be\(^{42,43}\)

\[
\begin{align*}
\lambda_{1,F} &:= (\tau_1 F, ..., \tau_{\min\{k,p\} F})' \in R^{\min\{k,p\}}, \\
\lambda_{2,F} &:= B_F \in R^{p \times p}, \\
\lambda_{3,F} &:= C_F \in R^{k \times k}, \\
\lambda_{4,F} &:= E_F G_i \in R^{k \times p}, \\
\lambda_{5,F} &:= E_F \left( \begin{array}{c} g_i \\ \text{vec}(G_i) \end{array} \right) \left( \begin{array}{c} g_i \\ \text{vec}(G_i) \end{array} \right)' \in R^{(p+1)k \times (p+1)k}, \\
\lambda_{6,F} &= (\lambda_{6,1,F}, ..., \lambda_{6,(\min\{k,p\}-1) F})' := \left( \frac{\tau_{2 F}}{\tau_{1 F}}, ..., \frac{\tau_{\min\{k,p\} F}}{\tau_{(\min\{k,p\}-1) F}} \right)' \in [0,1]^{\min\{k,p\}-1}, \text{ where } 0/0 := 0, \\
\lambda_{7,F} &:= W_2 F, \\
\lambda_{8,F} &:= U_2 F, \\
\lambda_{9,F} &:= F, \text{ and} \\
\lambda &= \lambda_F := (\lambda_{1,F}, ..., \lambda_{9,F}). \tag{16.16}
\end{align*}
\]

The dimensions of \(W_2 F\) and \(U_2 F\) depend on the choices of \(\widehat{W}_{n} = W_1(\widehat{W}_{2n})\) and \(\widehat{U}_{n} = U_1(\widehat{U}_{2n})\). We let \(\lambda_{5,gF}\) denote the upper left \(k \times k\) submatrix of \(\lambda_{5,F}\). Thus, \(\lambda_{5,gF} = E_F g_i g_i' = \Omega_F\). We consider two parameter spaces for \(\lambda\): \(\Lambda_{WU}\) and \(\Lambda_{WU,P}\), which correspond to \(\mathcal{F}_{WU}\) and \(\mathcal{F}_{WU} \cap \mathcal{F}_P\), respectively, where \(\mathcal{F}_P\) and \(\mathcal{F}_{WU}\) are defined in \(\text{(16.1)}\) and \(\text{(16.12)}\), respectively. The space \(\Lambda_{WU}\) is used for the CQLR test. The space \(\Lambda_{WU,P}\) is used for the CQLR\(_P\) test.\(^{44}\) The parameter spaces \(\Lambda_{WU}\) and

\(^{42}\)For simplicity, when writing \(\lambda = (\lambda_{1,F}, ..., \lambda_{9,F})\), we allow the elements to be scalars, vectors, matrices, and distributions and likewise in similar expressions.

\(^{43}\)If \(p = 1\), no vector \(\lambda_{6,F}\) appears in \(\lambda\) because \(\lambda_{1,F}\) only contains a single element.

\(^{44}\)Note that the parameter \(\lambda\) has different meanings for the CQLR and CQLR\(_P\) tests because \(U_2 F\) is different for the two tests.
\( \Lambda_{W,U,P} \) and the function \( h_n(\lambda) \) are defined by

\[
\Lambda_{W,U} := \{ \lambda : \lambda = (\lambda_{1,F},...,\lambda_{9,F}) \text{ for some } F \in \mathcal{F}_{W,U} \},
\]

\[
\Lambda_{W,U,P} := \{ \lambda : \lambda = (\lambda_{1,F},...,\lambda_{9,F}) \text{ for some } F \in \mathcal{F}_{W,U} \cap \mathcal{F}_P \}, \text{ and }
\]

\[
h_n(\lambda) := (n^{1/2}\lambda_{1,F},\lambda_{2,F},\lambda_{3,F},\lambda_{4,F},\lambda_{5,F},\lambda_{6,F},\lambda_{7,F},\lambda_{8,F}).
\] (16.17)

By the definition of \( \mathcal{F} \), \( \Lambda_{W,U} \) and \( \Lambda_{W,U,P} \) index distributions that satisfy the null hypothesis \( H_0 : \theta = \theta_0 \). The dimension \( J \) of \( h_n(\lambda) \) equals the number of elements in \( (\lambda_{1,F},...,\lambda_{8,F}) \). Redundant elements in \( (\lambda_{1,F},...,\lambda_{8,F}) \), such as the redundant off-diagonal elements of the symmetric matrix \( \lambda_{5,F} \), are not needed, but do not cause any problem.

We define \( \lambda \) and \( h_n(\lambda) \) as in (16.16) and (16.17) because, as shown below, the asymptotic distributions of the test statistics under a sequence \( \{F_n : n \geq 1\} \) for which \( h_n(\lambda_{F_n}) \rightarrow h \in H \) depend on the behavior of \( \lim n^{1/2}\lambda_{1,F_n} \), as well as \( \lim \lambda_{m,F_n} \) for \( m = 2,...,8 \). Note that \( \lambda_{1,F} \) measures the strength of identification.

For notational convenience,

\[
\{\lambda_{n,h} : n \geq 1\} \text{ denotes a sequence } \{\lambda_n \in \Lambda_{W,U} : n \geq 1\} \text{ for which } h_n(\lambda_n) \rightarrow h \in H
\] (16.18)

for \( H \) defined in (16.2) with \( \Lambda \) equal to \( \Lambda_{W,U} \). By the definitions of \( \Lambda_{W,U} \) and \( \mathcal{F}_{W,U} \), \( \{\lambda_{n,h} : n \geq 1\} \) is a sequence of distributions that satisfies the null hypothesis \( H_0 : \theta = \theta_0 \).

We decompose \( h \) (defined by (16.2), (16.16), and (16.17)) analogously to the decomposition of the first eight components of \( \lambda : h = (h_1,...,h_8) \), where \( \lambda_{m,F} \) and \( h_m \) have the same dimensions for \( m = 1,...,8 \). We further decompose the vector \( h_1 \) as \( h_1 = (h_{1,1},...,h_{1,\min(k,p)})' \), where the elements of \( h_1 \) could equal \( \infty \). We decompose \( h_6 \) as \( h_6 = (h_{6,1},...,h_{6,\min(k,p)-1})' \). In addition, we let \( h_{5,g} \) denote the upper left \( k \times k \) submatrix of \( h_5 \). In consequence, under a sequence \( \{\lambda_{n,h} : n \geq 1\} \), we have

\[
n^{1/2}r_{F_n} \rightarrow h_{1,j} \geq 0 \ \forall j \leq \min\{k,p\}, \ \lambda_{m,F_n} \rightarrow h_m \ \forall m = 2,...,8,
\]

\[
\lambda_{5,g,F_n} = \Omega_{F_n} = E_{F_n}g_tg_t' \rightarrow h_{5,g}, \ \text{and} \ \lambda_{6,j,F_n} \rightarrow h_{6,j} \ \forall j = 1,...,\min\{k,p\} - 1. \] (16.19)

By the conditions in \( \mathcal{F} \), defined in (16.1), \( h_{5,g} \) is pd.

\[\text{Analogously, for any subsequence } \{w_n : n \geq 1\}, \{\lambda_{w_n,h} : n \geq 1\} \text{ denotes a sequence } \{\lambda_{w_n} \in \Lambda : n \geq 1\} \text{ for which } h_{w_n}(\lambda_{w_n}) \rightarrow h \in H.\]
16.5 Assumption WU

We assume that the random weight matrices \( \hat{W}_n = W_1(\hat{W}_2) \) and \( \hat{U}_n = U_1(\hat{U}_2) \) defined in (16.4) satisfy the following assumption that depends on a suitably chosen parameter space \( \Lambda_\ast \subset \Lambda_{WU} \), such as \( \Lambda_{WU} \) or \( \Lambda_{WU,P} \).

**Assumption WU for the parameter space \( \Lambda_\ast \subset \Lambda_{WU} \):** Under all subsequences \( \{w_n\} \) and all sequences \( \{w_n; h_n\} \) with \( w_n; h_n \),

(a) \( \hat{W}_{2w_n} \to_p h_7 := \lim W_{2F_{wn}} \),

(b) \( \hat{U}_{2w_n} \to_p h_8 := \lim U_{2F_{wn}} \), and

(c) \( W_1(\cdot) \) is a continuous function at \( h_7 \) on some set \( \mathcal{W}_2 \) that contains \( \{\lambda_{7,F} (= W_{2F}) : \lambda = (\lambda_{1,F}, ..., \lambda_{9,F}) \in \Lambda_\ast\} \) and contains \( \hat{W}_{2w_n} \) wp→1 and \( U_1(\cdot) \) is a continuous function at \( h_8 \) on some set \( \mathcal{U}_2 \) that contains \( \{\lambda_{8,F} (= U_{2F}) : \lambda = (\lambda_{1,F}, ..., \lambda_{9,F}) \in \Lambda_\ast\} \) and contains \( \hat{U}_{2w_n} \) wp→1.

In Assumption WU and elsewhere below, “all sequences \( \{\lambda_{w_n,h} : n \geq 1\} \)” means “all sequences \( \{\lambda_{w_n,h} : n \geq 1\} \) for any \( h \in H \),” where \( H \) is defined in (16.2) with \( \Lambda \) equal to \( \Lambda_{WU} \), and likewise with \( n \) in place of \( w_n \).

Assumption WU for the parameter spaces \( \Lambda_{WU} \) and \( \Lambda_{WU,P} \) is verified in Lemma 27.4 in Section 27 below for the CQLR and CQLR\_P tests, respectively.

16.6 Asymptotic Distributions

This section provides the asymptotic distributions of QLR and QLR\_P test statistics and corresponding conditioning statistics. These statistics are used in the proof of Theorem 16.1 to verify Assumption B\_\* of Proposition 16.3.

For any \( F \in \mathcal{F} \), define

\[
\Phi_F^{vec(G_i)} := Var_F(vec(G_i)) - (E_Fvec(G_i)g_i')\Omega_F^{-1}g_i) \quad \text{and} \quad \Phi_h^{vec(G_i)} := \lim_{F_{wn}} \Phi_{F_{wn}}^{vec(G_i)}
\]

(16.20)

whenever the limit exists, where the distributions \( \{F_{wn} : n \geq 1\} \) correspond to \( \{\lambda_{wn,h} : n \geq 1\} \) for any subsequence \( \{w_n : n \geq 1\} \). The assumptions allow \( \Phi_h^{vec(G_i)} \) to be singular.

By the CLT and some straightforward calculations, the joint asymptotic distribution of \( n^{1/2}(\hat{g}_n', vec(\hat{D}_n - E_{F_n}G_i)') \) under \( \{\lambda_{n,h} : n \geq 1\} \) is given by

\[
\left( \begin{array}{c}
\bar{h}_h \\
vec(\bar{D}_h)
\end{array} \right) \sim N \left( 0^{(p+1)k}, \begin{pmatrix} h_{5,g} & 0^{k \times pk} \\
0^{pk \times k} & \Phi_h^{vec(G_i)} \end{pmatrix} \right),
\]

(16.21)
where $\bar{g}_h \in R^k$ and $\bar{D}_h \in R^{k \times p}$ are independent by the definition of $\bar{D}_n$, see Lemma 16.4 below.

To determine the asymptotic distributions of the $QLR_n$ and $QLR_{P_n}$ statistics (defined in (5.7) and just below (15.6)) and the conditional critical value of the CQLR and CQLR$_p$ tests (defined in (5.8), (5.9), and (15.7)), we need to determine the asymptotic distribution of $W_{F_n} \bar{D}_n U_{F_n}$ without recentering by $E_{F_n} G_i$. To do so, we post-multiply $W_{F_n} \bar{D}_n U_{F_n}$ first by $B_{F_n}$ and then by a nonrandom diagonal matrix $S_n \in R^{p \times p}$ (which may depend on $F_n$ and $h$). The matrix $S_n$ rescales the columns of $W_{F_n} \bar{D}_n U_{F_n} B_{F_n}$ to ensure that $n^{1/2} W_{F_n} \bar{D}_n U_{F_n} B_{F_n} S_n$ converges in distribution to a (possibly) random matrix that is finite a.s. and not a.s. zero.

The following is an important definition for the scaling matrix $S_n$ and asymptotic distributions given below. Consider a sequence $\{\lambda_{n,h} : n \geq 1\}$. Let $q = q_h (\in \{0, ..., \min\{k, p\}\})$ be such that

$$h_{1,j} = \infty \text{ for } 1 \leq j \leq q_h \text{ and } h_{1,j} < \infty \text{ for } q_h + 1 \leq j \leq \min\{k, p\},$$

(16.22)

where $h_{1,j} := \lim n^{1/2} \tau_{jF_n} \geq 0$ for $j = 1, ..., \min\{k, p\}$ by (16.19) and the distributions $\{F_n : n \geq 1\}$ correspond to $\{\lambda_{n,h} : n \geq 1\}$ defined in (16.18). This value $q$ exists because $\{h_{1,j} : j \leq \min\{k, p\}\}$ are nonincreasing in $j$ (since $\{\tau_{jF} : j \leq \min\{k, p\}\}$ are nonincreasing in $j$, as defined in (16.15)). Note that $q$ is the number of singular values of $W_{F_n} (E_{F_n} G_i) U_{F_n}$ that diverge to infinity when multiplied by $n^{1/2}$. Heuristically, $q$ is the maximum number of parameters, or one-to-one transformations of the parameters, that are strongly or semi-strongly identified. (That is, one could partition $\theta$, or a one-to-one transformation of $\theta$, into subvectors of dimension $q$ and $p - q$ such that if the $p - q$ subvector was known and, hence, was no longer part of the parameter, then the $q$ subvector would be strongly or semi-strongly identified in the sense used in this paper.)

Let

$$S_n := \text{Diag}\{n^{1/2} \tau_{1F_n}^{-1}, ..., (n^{1/2} \tau_{qF_n})^{-1}, 1, ..., 1\} \in R^{p \times p} \text{ and } T_n := B_{F_n} S_n \in R^{p \times p},$$

(16.23)

where $q = q_h$ is defined in (16.22). Note that $S_n$ is well defined for $n$ large, because $n^{1/2} \tau_{jF_n} \to \infty$ for all $j \leq q$.

The asymptotic distribution of $\bar{D}_n$ after suitable rotations and rescaling, but without recentering (by subtracting $E_{F_n} G_i$), depends on the following quantities. We partition $h_2$ and $h_3$ and define $\bar{\Delta}_h$
Suppose Assumption SM to AG1 as Lemma 10.3. The following lemma allows for

\[ h_2 = (h_{2,q}, h_{2,p-q}), \quad h_3 = (h_{3,q}, h_{3,k-q}), \]

\[ h_{R, q-p}^\circ := \begin{bmatrix} 0^{p} \times (p-q) \\ \text{Diag}\{h_{1,q+1}, \ldots, h_{1,p}\} \\ 0^{(k-p)} \times (p-q) \end{bmatrix} \in \mathbb{R}^{k \times (p-q)} \text{ if } k \geq p, \]

\[ h_{R, q-p} \in \begin{bmatrix} 0^{q} \times (k-q) \\ \text{Diag}\{h_{1,q+1}, \ldots, h_{1,k}\} \\ 0^{(k-q)} \times (p-k) \end{bmatrix} \in \mathbb{R}^{k \times (p-q)} \text{ if } k < p, \]

\[ \Delta_h = (\Delta_{h,q}, \Delta_{h,p-q}) \in \mathbb{R}^{k \times p}, \quad \Delta_{h,q} := h_{3,q}, \quad \Delta_{h,p-q} := h_{3}h_{1,p-q} + h_{71}D_h h_{81}h_{2,p-q}, \]

\[ h_{71} := W_1(h_7), \quad \text{and} \quad h_{81} := U_1(h_8), \quad (16.24) \]

where \( h_{2,q} \in \mathbb{R}^{p \times q}, \) \( h_{2,p-q} \in \mathbb{R}^{p \times (p-q)}, \) \( h_{3,q} \in \mathbb{R}^{k \times q}, \) \( h_{3,k-q} \in \mathbb{R}^{k \times (k-q)}, \) \( \Delta_{h,q} \in \mathbb{R}^{k \times q}, \) \( \Delta_{h,p-q} \in \mathbb{R}^{k \times (p-q)}, \) \( h_{71} \in \mathbb{R}^{k \times k}, \) and \( h_{81} \in \mathbb{R}^{p \times p}. \) Note that when Assumption WU holds \( h_{71} = \lim W_{F_n} = \lim W_1(W_{2F_n}) \) and \( h_{81} = \lim U_{F_n} = \lim U_1(U_{2F_n}) \) under \( \{\lambda_{n,h} : n \geq 1\}. \)

The following lemma allows for \( k \geq p \) and \( k < p. \) For the case where \( k \geq p, \) it appears in the SM to AG1 as Lemma 10.3.

**Lemma 16.4** Suppose Assumption WU holds for some non-empty parameter space \( \Lambda_s \subset \Lambda_{WU}. \) Under all sequences \( \{\lambda_{n,h} : n \geq 1\} \) with \( \lambda_{n,h} \in \Lambda_s, \)

\[ n^{1/2}(\tilde{g}_n, \tilde{D}_n - E_{F_n}G_t, W_{F_n}\tilde{D}_n U_{F_n}T_n) \rightarrow_d (\tilde{g}_h, \tilde{D}_h, \Delta_h), \]

where (a) \( (\tilde{g}_h, \tilde{D}_h) \) are defined in (16.21), (b) \( \Delta_h \) is the nonrandom function of \( h \) and \( \tilde{D}_h \) defined in (16.24), (c) \( (\Delta_h, \tilde{D}_h) \) and \( \tilde{g}_h \) are independent, and (d) under all subsequences \( \{w_n\} \) and all sequences \( \{\lambda_{w_n,h} : n \geq 1\} \) with \( \lambda_{w_n,h} \in \Lambda_s, \) the convergence result above and the results of parts (a)-(c) hold with \( n \) replaced with \( w_n. \)

**Comments:** (i) **Lemma 16.4(c)** is a key property that leads to the correct asymptotic size of the CQLR and CQLR_{P} tests.

(ii) **Lemma 10.3** in the SM to AG1 contains a part (part (d)), which does not appear in **Lemma 16.4**. It states that \( \Delta_h \) has full column rank a.s. under some additional conditions. For Kleibergen’s (2005) LM statistic and Kleibergen’s (2005) CLR statistics that employ it, which are considered in AG1, one needs the (possibly) random limit matrix of \( n^{1/2}W_{F_n}\tilde{D}_n U_{F_n}B_{F_n}S_n, \) viz., \( \Delta_h, \) to have full column rank with probability one, in order to apply the continuous mapping theorem (CMT), which

\[ ^{47} \text{There is some abuse of notation here. E.g., } h_{2,q} \text{ and } h_{2,p-q} \text{ denote different matrices even if } p - q \text{ happens to equal } q. \]
is used to determine the asymptotic distribution of the test statistics. To obtain this full column rank property, AG1 restricts the parameter space for the tests based on aforementioned statistics to be a subset \( \mathcal{F}_0 \) of \( \mathcal{F} \), where \( \mathcal{F}_0 \) is defined in Section 3 of AG1. In contrast, the \( QLR_n \) and \( QLR_{P_n} \) statistics considered here do not depend on Kleibergen’s LM statistic and do not require the asymptotic distribution of \( n^{1/2}W_{F_n}\bar{D}_nU_{F_n}B_{F_n}S_n \) to have full column rank a.s. In consequence, it is not necessary to restrict the parameter space from \( \mathcal{F} \) to \( \mathcal{F}_0 \) when considering these statistics.

Let

\[
\hat{\kappa}_{jn} \text{ denote the } j\text{th eigenvalue of } n\hat{U}_n'\hat{D}_n'\hat{W}_n\hat{W}_n\hat{D}_n\hat{U}_n, \forall j = 1, ..., p, \tag{16.25}
\]

ordered to be nonincreasing in \( j \). The \( j \)th singular value of \( n^{1/2}\hat{W}_n\hat{D}_n\hat{U}_n \) equals \( \hat{\kappa}_{j/n}^{1/2} \) for \( j = 1, ..., \min\{k, p\} \).

The following proposition, combined with Lemma 16.2, is used to determine the asymptotic behavior of the data-dependent conditional critical values of the CQLR and CQLR\(_P\) tests. The proposition is the same as Theorem 10.4(c)-(f) in the SM to AG1, except that it is extended to cover the case \( k < p \), not just \( k \geq p \). For brevity, the proof of the proposition given in Section 25 below just describes the changes needed to the proof of Theorem 10.4(c)-(f) in the SM to AG1 in order to cover the case \( k < p \). The proof of Theorem 10.4(c)-(f) in the SM to AG1 is similar to, but simpler than, the proof of Theorem 16.6 below, which is given in Section 26.

**Proposition 16.5** Suppose Assumption WU holds for some non-empty parameter space \( \Lambda_* \subset \Lambda_{WU} \). Under all sequences \( \{\lambda_n, h : n \geq 1\} \) with \( \lambda_n, h \in \Lambda_* \),

(a) \( \hat{\kappa}_{jn} \to_p \infty \) for all \( j \leq q \),

(b) the (ordered) vector of the smallest \( p-q \) eigenvalues of \( n\hat{U}_n'\hat{D}_n'\hat{W}_n\hat{W}_n\hat{D}_n\hat{U}_n \), i.e., \( (\hat{\kappa}_{(q+1)n}, ..., \hat{\kappa}_{pn})' \), converges in distribution to the (ordered) \( p-q \) vector of the eigenvalues of \( \sqrt{n}h_{3,k-q}h_{3,k-q}^*\Delta_{h,p-q} \times (p-q) \times (p-q) \),

(c) the convergence in parts (a) and (b) holds jointly with the convergence in Lemma 16.4, and

(d) under all subsequences \( \{w_n\} \) and all sequences \( \{\lambda_{w_n, h} : n \geq 1\} \) with \( \lambda_{w_n, h} \in \Lambda_* \), the results in parts (a)-(c) hold with \( n \) replaced with \( w_n \).

**Comment:** Proposition 16.5(a) and (b) with \( \hat{W}_n = \hat{\Omega}_n^{-1/2} \) and \( \hat{U}_n = \hat{L}_n^{1/2} \) is used to determine the asymptotic behavior of the critical value function for the CQLR test, which depends on \( n^{1/2}\hat{D}_n^* \) defined in (15.7), see the proof of Theorem 27.1 in Section 27.2. Proposition 16.5(a) and (b) with \( \hat{W}_n = \hat{\Omega}_n^{-1/2} \) and \( \hat{U}_n = \hat{L}_n^{1/2} \) is used to determine the asymptotic behavior of the critical value function for the CQLR\(_P\) test, which depends on \( n^{1/2}\hat{D}_n^* \) defined in (15.6), see the proof of Theorem 27.1 in Section 27.2.
The next theorem provides the asymptotic distribution of the general $QLR_{WU,n}$ statistic defined in (16.3) and, as special cases, those of the $QLR_n$ and $QLR_{P,n}$ statistics.

**Theorem 16.6** Suppose Assumption WU holds for some non-empty parameter space $\Lambda_* \subset \Lambda_{WU}$. Under all sequences $\{\lambda_{n,h} : n \geq 1\}$ with $\lambda_{n,h} \in \Lambda_*$,

$$QLR_{WU,n} \rightarrow_d g_h^{-1}h_{5,g}^{-1}\bar{g}_h - \lambda_{\min}((\bar{\Sigma}_{h,p-q}, h_{5,g}^{-1/2}\bar{g}_h)'h_{3,k-q}h_{3,k-q}^{-1}(\bar{\Sigma}_{h,p-q}, h_{5,g}^{-1/2}\bar{g}_h))$$

and the convergence holds jointly with the convergence in Lemma 16.4 and Proposition 16.5. When $q = p$ (which can only hold if $k \geq p$ because $q \leq \min\{k, p\}$), $\bar{\Sigma}_{h,p-q}$ does not appear in the limit random variable and the limit random variable reduces to $(h_{5,g}^{-1/2}\bar{g}_h)'h_{3,p}h_{3,p}^{-1/2}\bar{g}_h \sim \chi_p^2$. When $q = k$ (which can only hold if $k \leq p$), the $\lambda_{\min}(\cdot)$ expression does not appear in the limit random variable and the limit random variable reduces to $g_h^{-1}h_{5,g}^{-1}\bar{g}_h \sim \chi_k^2$. When $k \leq p$ and $q < k$, the $\lambda_{\min}(\cdot)$ expression equals zero and the limit random variable reduces to $g_h^{-1}h_{5,g}^{-1}\bar{g}_h \sim \chi_k^2$. Under all subsequences $\{w_n\}$ and all sequences $\{\lambda_{w_n,h} : n \geq 1\}$ with $\lambda_{w_n,h} \in \Lambda_*$, the same results hold with $n$ replaced with $w_n$.

**Comments:** (i) Theorem 16.6 gives the asymptotic distributions of the $QLR_n$ and $QLR_{P,n}$ statistics (defined by (5.7) and (15.6), respectively) once it is verified that the choices of $(\bar{W}_n, \bar{U}_n)$ for these statistics satisfy Assumption WU for the parameter spaces $\Lambda_{WU}$ and $\Lambda_{WU,P}$, respectively. The latter is done in Lemma 27.4 in Section 27.1.

(ii) When $q = p$, the parameter $\theta_0$ is strongly or semi-strongly identified and Theorem 16.6 shows that the $QLR_{WU,n}$ statistic has a $\chi_p^2$ asymptotic null distribution.

(iii) When $k = p$, Theorem 16.6 shows that the $QLR_{WU,n}$ statistic has a $\chi_k^2$ asymptotic null distribution regardless of the strength of identification.

(iv) When $k < p$, $\theta$ is necessarily unidentified and Theorem 16.6 shows that the asymptotic null distribution of $QLR_{WU,n}$ is $\chi_k^2$.

(v) The proof of Theorem 16.6 given in Section 26 also shows that the largest $q$ eigenvalues of $n(\bar{W}_n\bar{D}_n\bar{U}_n, \bar{\Omega}_n^{-1/2}\bar{g}_n)'(\bar{W}_n\hat{D}_n\hat{U}_n, \hat{\Omega}_n^{-1/2}\hat{g}_n)$ diverge to infinity in probability and the (ordered) vector of the smallest $p+1-q$ eigenvalues of this matrix converges in distribution to the (ordered) vector of the $p+1-q$ eigenvalues of $(\bar{\Sigma}_{h,p-q}, h_{5,g}^{-1/2}\bar{g}_h)'h_{3,k-q}h_{3,k-q}^{-1}(\bar{\Sigma}_{h,p-q}, h_{5,g}^{-1/2}\bar{g}_h)$.

Propositions 16.3 and 16.5 and Theorem 16.6 are used to prove Theorem 16.1. The proof is given in Section 27 below. Note, however, that the proof is not a straightforward implication of these results. The proof also requires (i) determining the behavior of the conditional critical value function $c_{k,p}(D, 1-\alpha)$, defined in the paragraph containing (5.8), for sequences of nonrandom
$k \times p$ matrices $\{D_n : n \geq 1\}$ whose singular values may converge or diverge to infinity at any rates, (ii) showing that the distribution function of the asymptotic distribution of the $QLR_{W,U,n}$ statistic, conditional on the asymptotic version of the conditioning statistic, is continuous and strictly increasing at its $1 - \alpha$ quantile for all possible $(k,p,q)$ values and all possible limits of the scaled population singular values $\{n^{1/2}r_{jF_n} : n \geq 1\}$ for $j = 1, \ldots, \min\{k,p\}$, and (iii) establishing that Assumption WU holds for the CQLR and CQLR$_P$ tests. These results are established in Lemmas 27.2, 27.3, and 27.4 respectively, in Section 27.

17 Singularity-Robust Tests

In this section, we prove the main Theorems 6.1 and 15.2 for the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests using Theorem 16.1 for the tests without the SR extension. These tests, defined in (4.7), (5.13), and (15.9), depend on the random variable $\tilde{r}_n(\theta)$ and random matrices $\tilde{A}_n(\theta)$ and $\tilde{A}_n^+(\theta)$, defined in (4.3) and (4.4). First, in the following lemma, we show that with probability that goes to one as $n \to \infty$ (wp→1), the SR test statistics and data-dependent critical values are the same as when the non-random and rescaled population quantities $r_F(\theta)$ and $\Pi_{1F}^{-1/2}(\theta)A_F(\theta)'$ are used to define these statistics, rather than $\tilde{r}_n(\theta)$ and $\tilde{A}_n(\theta)'$, where $r_F(\theta)$, $A_F(\theta)$, and $\Pi_{1F}(\theta)$ are defined as in (3.4) and (3.5). The lemma also shows that the extra rejection condition in (4.7), (5.13), and (15.9) fails to hold wp→1 under all sequences of null distributions.

In the following lemma, $\theta_{0n}$ is the true value that may vary with $n$ (which is needed for the CS results) and col(·) denotes the column space of a matrix.

**Lemma 17.1** For any sequence $\{(F_n, \theta_{0n}) \in \mathcal{F}^{SR}_{\Theta:AR} : n \geq 1\}$, (a) $\tilde{r}_n(\theta_{0n}) = r_{F_n}(\theta_{0n})$ wp→1, (b) $\text{col}(\tilde{A}_n(\theta_{0n})) = \text{col}(A_{F_n}(\theta_{0n}))$ wp→1, (c) the statistics $SR$-AR$_n(\theta_{0n})$, $SR$-QLR$_n(\theta_{0n})$, $SR$-QLR$_P(\theta_{0n})$, $\tilde{c}_F(\theta_{0n}), \tilde{c}_F(\theta_{0n})_d(n^{1/2}\tilde{D}^*_{An}(\theta_{0n}), 1 - \alpha)$, and $c_{\tilde{F}_n}(\theta_{0n})_d(n^{1/2}\tilde{D}^*_{An}(\theta_{0n}), 1 - \alpha)$ are invariant wp→1 to the replacement of $\tilde{r}_n(\theta_{0n})$ and $\tilde{A}_n(\theta_{0n})'$ by $r_{F_n}(\theta_{0n})$ and $\Pi_{1F_n}^{-1/2}(\theta_{0n})A_{F_n}(\theta_{0n})'$, respectively, and (d) $\tilde{A}_n(\theta_{0n})', \tilde{g}_n(\theta_{0n}) = 0^{k - \tilde{r}_n(\theta_{0n})}$ wp→1, where this equality is defined to hold when $\tilde{r}_n(\theta_{0n}) = k$.

**Comments.** 1. We now provide an example that appears to be a counter-example to the claim that $\tilde{r}_n = r$ wp→1. We show that it is not a counter-example because the distributions considered violate the moment bound in $\mathcal{F}^{SR}_{\Theta:AR}$ in (3.6). Suppose $k = 1$ and $g_i = 1, -1, 0$ with probabilities $p_n/2$, $p_n/2$, and $1 - p_n$, respectively, under $F_n$, where $p_n = c/n$ for some $0 < c < \infty$. Then, $E_{F_n}g_i = 0$, as is required, and $rk(\Omega_{F_n}) = rk(E_{F_n}g_i^2) = rk(p_n) = 1$. We have $\tilde{\Omega}_n = 0$ if $g_i = 0 \forall i \leq n$. The latter holds with probability $(1 - p_n)^n = (1 - c/n)^n \to e^{-c} > 0$ as $n \to \infty$. In consequence, $P_{F_n}(rk(\tilde{\Omega}_n) = rk(\Omega_{F_n})) = P_{F_n}(rk(\tilde{\Omega}_n) = 1) \leq 1 - P_{F_n}(g_i = 0 \forall i \leq n) \to 1 - e^{-c} < 1$,
which is inconsistent with the claim that \( \hat{r}_n = r \) \( \text{wp} \to 1 \). However, the distributions \( \{F_n : n \geq 1\} \) in this example violate the moment bound \( E_F[|\Pi_{1Ф}^{-1/2}A'_Фg_i|^2]^{\gamma} \leq M \) in \( \mathcal{F}_{AR}^{SR} \), so there is no inconsistency with the claim. This holds because for these distributions \( E_F[|\Pi_{1Ф}^{-1/2}A'_Фg_i|^2]^{\gamma} = E_F[|\alpha_i^{-1/2}(gi)gi|^{2}\gamma] = p_n^{-(2+\gamma)/2}E_F|gi| = p_n^{\gamma/2} \to \infty \) as \( n \to \infty \), where the second equality uses \( |gi| \) equals 0 or 1 and the third equality uses \( E_F|gi| = p_n \).

2. The example in the previous comment is extreme. A simple version of a more typical example where singularity and near singularity may occur is the case where \( W_i \sim \text{iid } N(\theta, \Omega_F) \) for \( \theta \in \mathbb{R}^k \), \( \Omega_F \in \mathbb{R}^{k \times k} \), \( g(W_i, \theta) := W_i - \theta, \Omega_F \) has spectral decomposition \( A_F\Pi_FA'_F \), and some eigenvalues of \( \Omega_F \) may be close to zero or equal to zero. In this case, \( \Pi_{1Ф}^{-1/2}A'_Фg_i \) is a vector of independent standard normal random variables and the moment conditions in \( \mathcal{F}_{AR}^{SR} \) and \( \mathcal{F}_{AR}^{SR} \) hold immediately.

In this case, the conditions in \( \mathcal{F}_{AR}^{SR} \) and \( \mathcal{F}_{AR}^{SR} \) are mild moment conditions that allow one to obtain asymptotic results without the normality assumption.

\textbf{Proof of Lemma [17.1]} For notational simplicity, we suppress the dependence of various quantities on \( \theta_{0n} \). By considering subsequences, it suffices to consider the case where \( r_{F_n} = r \) for all \( n \geq 1 \) for some \( r \in \{0, 1, \ldots, k\} \).

First, we establish part (a). We have \( \hat{r}_n \leq r \) a.s. for all \( n \geq 1 \) because for any constant vector \( \lambda \in \mathbb{R}^k \) for which \( \lambda'\Omega_{0n} \lambda = 0 \), we have \( \lambda'g_i = 0 \) a.s.\( [F_n] \) and \( \lambda'\hat{\Omega}_{0n} \lambda = n^{-1} \sum_{i=1}^n (\lambda'g_i)^2 - (\lambda'g_n)^2 = 0 \) a.s.\( [F_n] \), where a.s.\( [F_n] \) means “with probability one under \( F_n \).” This completes the proof of part (a) when \( r = 0 \). Hence, for the rest of the proof of part (a), we assume \( r > 0 \).

We have \( \hat{r}_n := r k(\hat{\Omega}_{0n}) \geq r k(\Pi_{1Ф}^{-1/2}A'_Ф\hat{\Omega}_{0n}A_F\Pi_{1Ф}^{-1/2}) \) because \( \hat{\Omega}_{0n} \) is \( k \times k \), \( A_{F_n}\Pi_{1Ф}^{-1/2} \) is \( k \times r \), and \( 1 \leq r \leq k \). In addition, we have

\[
\Pi_{1Ф}^{-1/2}A'_Ф\hat{\Omega}_{0n}A_F\Pi_{1Ф}^{-1/2} = n^{-1} \sum_{i=1}^n (\Pi_{1Ф}^{-1/2}A'_Фg_i)(\Pi_{1Ф}^{-1/2}A'_Фg_i)' - (n^{-1} \sum_{i=1}^n \Pi_{1Ф}^{-1/2}A'_Фg_i)(n^{-1} \sum_{i=1}^n \Pi_{1Ф}^{-1/2}A'_Фg_i)',
\]

\[
E_F(\Pi_{1Ф}^{-1/2}A'_Фg_i)(\Pi_{1Ф}^{-1/2}A'_Фg_i)' = \Pi_{1Ф}^{-1/2}A'_Ф\Omega_{0n}A_F\Pi_{1Ф}^{-1/2} = \Pi_{1Ф}^{-1/2}A'_ФA^\Omega_F\Pi_{1Ф}A_F\Pi_{1Ф}^{-1/2} = I_r,
\]

and \( E_F\Pi_{1Ф}^{-1/2}A'_Фg_i = 0 \), where the second last equality in (17.1) holds by the spectral decomposition in (3.4) and the last equality in (17.1) holds by the definitions of \( A^\Omega_F \), \( A_F \), and \( \Pi_{1Ф} \) in (3.4) and (3.5). By (17.1), the moment conditions in \( \mathcal{F}_{AR}^{SR} \), and the weak law of large numbers for \( L^{1+\gamma/2} \)-bounded i.i.d. random variables for \( \gamma > 0 \), we obtain \( \Pi_{1Ф}^{-1/2}A'_Ф\hat{\Omega}_{0n}A_F\Pi_{1Ф}^{-1/2} \to_p I_r \). In consequence, \( r k(\Pi_{1Ф}^{-1/2}A'_Ф\hat{\Omega}_{0n}A_F\Pi_{1Ф}^{-1/2}) \geq r \) \( \text{wp} \to 1 \), which concludes the proof that \( \hat{r}_n = r \).
Next, we prove part (b). Let \( N(\cdot) \) denote the null space of a matrix. We have

\[
\lambda \in N(\Omega_{F_n}) \implies \lambda'\Omega_{F_n}\lambda = 0 \implies Var_{F_n}(\lambda'g_i) = 0 \implies \lambda'g_i = 0 \ 	ext{a.s.}[F_n] \\
\implies \hat{\Omega}_n\lambda = 0 \ 	ext{a.s.}[F_n] \implies \lambda \in N(\hat{\Omega}_n) \ 	ext{a.s.}[F_n].
\]

(17.2)

That is, \( N(\Omega_{F_n}) \subset N(\hat{\Omega}_n) \ 	ext{a.s.}[F_n] \). This and \( rk(\Omega_{F_n}) = rk(\hat{\Omega}_n) \ \text{wp} \rightarrow 1 \) imply that \( N(\Omega_{F_n}) = N(\hat{\Omega}_n) \ \text{wp} \rightarrow 1 \) (because if \( N(\hat{\Omega}_n) \) is strictly larger than \( N(\Omega_{F_n}) \) then the dimension and rank of \( \hat{\Omega}_n \) must exceed the dimension and rank of \( N(\Omega_{F_n}) \), which is a contradiction). In turn, \( N(\Omega_{F_n}) = N(\hat{\Omega}_n) \ \text{wp} \rightarrow 1 \) implies that \( \text{col}(\hat{A}_n) = \text{col}(A_{F_n}) \ \text{wp} \rightarrow 1 \), which proves part (b).

To prove part (c), it suffices to consider the case where \( r \geq 1 \) because the test statistics and their critical values are all equal to zero by definition when \( \tilde{r}_n = 0 \) and \( \tilde{r}_n = 0 \ \text{wp} \rightarrow 1 \) when \( r = 0 \) by part (a). Part (b) of the Lemma implies that there exists a random \( r \times r \) nonsingular matrix \( \hat{M}_n \) such that

\[
\hat{A}_n = A_{F_n} \Pi_{1F_n}^{-1/2} \hat{M}_n \ \text{wp} \rightarrow 1,
\]

(17.3)

because \( \Pi_{1F_n} \) is nonsingular (since it is a diagonal matrix with the positive eigenvalues of \( \Omega_{F_n} \) on its diagonal by its definition following (3.5)). Equation (17.3) and \( \tilde{r}_n = r \ \text{wp} \rightarrow 1 \) imply that the statistics \( SR-AR_n, SR-QLR_n, SR-QLR_{F_P} \), \( c_{F_n}(n^{1/2}\hat{D}_{An}^*, 1 - \alpha) \), and \( c_{\hat{n}_{F_F}}(n^{1/2}\hat{D}_{An}^*, 1 - \alpha) \) are invariant \( \text{wp} \rightarrow 1 \) to the replacement of \( \tilde{r}_n \) and \( \hat{A}_n \) by \( r \) and \( \Pi_{1F_n}^{-1/2}A_{F_n} \), respectively. Now we apply the invariance results of Lemmas 5.1 and 15.1 with \( (k, g_i, G_i) \) replaced by \( (r, \Pi_{1F_n}^{-1/2}A_{F_n}g_i, \Pi_{1F_n}^{-1/2}A_{F_n}G_i) \) and with \( M \) equal to \( \hat{M}_n \). These results imply that the previous five statistics when based on \( r \) and \( \Pi_{1F_n}^{-1/2}A_{F_n}g_i \) are invariant to the multiplication of the moments \( r^{1/2}A_{F_n}g_i \) by the nonsingular matrix \( \hat{M}_n \). Thus, these five statistics, defined as in Sections 5.2 and 15, are invariant \( \text{wp} \rightarrow 1 \) to the replacement of \( \tilde{r}_n \) and \( \hat{A}_n \) by \( r \) and \( \Pi_{1F_n}^{-1/2}A_{F_n} \), respectively.

Lastly, we prove part (d). The equality \( (\hat{A}_n^*)^g_i = 0^{k - \tilde{r}_n} \) holds by definition when \( \tilde{r}_n = k \) (see the statement of Lemma 17.1(d)) and \( \tilde{r}_n = r \ \text{wp} \rightarrow 1 \). Hence, it suffices to consider the case where

\[wp \rightarrow 1.\]
For all $n \geq 1$, we have $E_{F_n}(A_{F_n}^r g_n) = 0^{k-r}$ and

$$nVar_{F_n}((A_{F_n}^r g_n) = (A_{F_n}^r \Omega_{F_n} A_{F_n}^r = (A_{F_n}^r \Pi_{F_n} (A_{F_n}^r)^r A_{F_n}^r = 0^{(k-r) \times (k-r)}, \quad (17.4)$$

where the second equality uses the spectral decomposition in (3.4) and the last equality uses $A_{F_n}^\Omega = [A_F, A_r^r]$, see (3.5). In consequence, $(A_{F_n}^r g_n) = 0^{k-r}$ a.s. This and and the result of part (b) that $\text{col}(\hat{A}_n^r) = \text{col}(A_{F_n}^r)$ wp→1 establish part (d). $\square$

Given Lemma (17.1(d)), the extra rejection conditions in the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests and CS’s (i.e., the second conditions in (4.7), (4.9), (5.13), (15.9), and in the SR-CQLR and SR-CQLR$_P$ CS definitions following (5.13) and (15.9)) can be ignored when computing the asymptotic size properties of these tests and CS’s (because the condition fails to hold for each test wp→1 under any sequence of null hypothesis values for any sequence of distributions in the null hypotheses, and the condition holds for each CS wp→1 under any sequence of true values $\theta_0$ for any sequence of distributions for which the moment conditions hold at $\theta_0$).

Given Lemma (17.1(c)), the asymptotic size properties of the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests and CS’s can be determined by the analogous tests and CS’s that are based on $r_{F_n}(\theta_0)$ and $\Pi_{F_n}^{-1/2}(\theta_0) A_{F_n}(\theta_0)^r$ (for fixed $\theta_0$ with tests and for any $\theta_0 \in \Theta$ with CS’s). For the tests, we do so by partitioning $\mathcal{F}_{SR}^{AR}$, $\mathcal{F}^{SR}$, and $\mathcal{F}_{SR}^{P}$ into $k$ sets based on the value of $r k(\Omega_F(\theta_0))$ and establishing the correct asymptotic size and asymptotic similarity of the analogous tests separately for each parameter space. That is, we write $\mathcal{F}_{AR}^{SR} = \cup_{r=0}^k \mathcal{F}_{AR[r]}^{SR}$, where $\mathcal{F}_{AR[r]}^{SR} := \{F \in \mathcal{F}_{AR[r]}^{SR} : r k(\Omega_F(\theta_0)) = r\}$, and establish the desired results for $\mathcal{F}_{AR[r]}^{SR}$ separately for each $r$. Analogously, we write $\mathcal{F}^{SR} = \cup_{r=0}^k \mathcal{F}^{SR}$ and $\mathcal{F}_{P[r]}^{SR} = \cup_{r=0}^k \mathcal{F}_{P[r]}^{SR}$, where $\mathcal{F}_{AR[r]}^{SR} := \mathcal{F}_{AR[r]}^{SR} \cap \mathcal{F}^{SR}$ and $\mathcal{F}_{P[r]}^{SR} := \mathcal{F}_{P[r]}^{SR} \cap \mathcal{F}^{SR}$. Note that we do not need to consider the parameter space $\mathcal{F}_{AR[r]}^{SR}$ for $r = 0$ for the SR-AR test when determining the asymptotic size of the SR-AR test because the test fails to reject $H_0$ wp→1 based on the first condition in (4.7) when $r = 0$ (since the test statistic and critical value equal zero by definition when $\tilde{t}_n = 0$ and $\tilde{t}_n = r = 0$ wp→1 by Lemma (17.1(a))). In addition, we do not need to consider the parameter space $\mathcal{F}_{AR[r]}^{SR}$ for $r = 0$ for the SR-AR test when determining the asymptotic similarity of the test because such distributions are excluded from the parameter space $\mathcal{F}_{AR}$ by the statement of Theorem (6.1). Analogous arguments regarding the parameter spaces corresponding to $r = 0$ apply to the other tests and CS’s. Hence, from here on, we assume $r \in \{1, \ldots, k\}$.

For given $r = r k(\Omega_F(\theta_0))$, the moment conditions and Jacobian are

$$g^*_{F_i} := \Pi_{1F}^{-1/2} A'_F g_i \text{ and } G^*_{F_i} := \Pi_{1F}^{-1/2} A'_F G_i, \quad (17.5)$$
where $A_F \in R^{k \times r}$, $\Pi_{1F} \in R^{r \times r}$, and dependence on $\theta_0$ is suppressed for notational simplicity.

Given the conditions in $\mathcal{F}^{SR}$, we have

$$
E_F\|g_{F,i}^r\|^{2+\gamma} = E_F\|\Pi_{1F}^{-1/2}A_F'g_i\|^{2+\gamma} \leq M,
$$

$$
E_F\|\text{vec}(G_{F,i}^r)\|^{2+\gamma} = E_F\|\text{vec}(\Pi_{1F}^{-1/2}A_F'G_i)\|^{2+\gamma} \leq M,
$$

$$
\lambda_{\min}(E_Fg_{F,i}^r;g_{F,i}^r) = \lambda_{\min}(\Pi_{1F}^{-1/2}A_F'\Omega_FA_F\Pi_{1F}^{-1/2}) = \lambda_{\min}(I_r) = 1,
$$

(17.6)

and $E_Fg_{F,i}^r = 0^r$, where the second equality in the third line of (17.6) holds by the spectral decomposition in (3.4) and the partition $A_F^\Omega = [A_F, A_F^\Omega]$ in (3.5). Thus, $F \in \mathcal{F}^{SR}_{[r]}$ implies that $F \in \mathcal{F}$ with $\delta \leq 1$, when $\mathcal{F}$ is defined with $(g_{F,i}^r, G_{F,i}^r)$ in place of $(g_i, G_i)$, where the definition of $\mathcal{F}$ in (16.1) is extended to allow $g_i$ and $G_i$ to depend on $F$. Now we apply Theorem 16.1 with $(g_{F,i}^r, G_{F,i}^r)$ and $r$ in place of $(g_i, G_i)$ and $k$ and with $\delta \leq 1$, to obtain the correct asymptotic size and asymptotic similarity of the SR-CQLR test for the parameter space $\mathcal{F}^{SR}_{[r]}$ for $r = 1, \ldots, k$. This requires that Theorem 16.1 holds for $k < p$, which it does. The fact that $g_{F,i}^r$ and $G_{F,i}^r$ depend on $F$, whereas $g_i$ and $G_i$ do not, does not cause a problem, because the proof of Theorem 16.1 goes through as is if $g_i$ and $G_i$ depend on $F$. This establishes the results of Theorem 6.1 for the SR-CQLR test. The proof for the SR-CQLR CS is essentially the same, but with $\theta_0$ taking any value in $\Theta$ and with $\mathcal{F}^{SR}_{\Theta}$ and $\mathcal{F}_\Theta$, defined in (3.7) and just below (16.1), in place of $\mathcal{F}^{SR}$ and $\mathcal{F}$, respectively.

The proof for the SR-AR test and CS is the same as that for the SR-CQLR test and CS, but with $\text{vec}(G_{F,i}^r)$ deleted in (17.6) and with the subscript AR added to the parameter spaces that appear.

Next, we consider the SR-CQLR$P$ test. When the moment functions satisfy (15.1), i.e., $g_i = u_iZ_i$, we define $Z_{F,i}^r := \Pi_{1F}^{-1/2}A_F'Z_i$, $g_{F,i}^r = u_iZ_{F,i}^r$, and $G_{F,i}^r = Z_{F,i}^ru_{\theta_i}'$, where $u_{\theta_i}$ is defined in (15.2) and the dependence of various quantities on $\theta_0$ is suppressed. In this case, by the conditions in $\mathcal{F}^{SR}_{P}$, the IV’s $Z_{F,i}^r$ satisfy $E_F\|Z_{F,i}^r\|^{4+\gamma} = E_F\|\Pi_{1F}^{-1/2}A_F'Z_i\|^{4+\gamma} \leq M$ and $E_F\|u_{i}^r\|^{2+\gamma} \leq M$, where $u_{i}^r := (u_i, u_{\theta_i}')$. Next we show that $\lambda_{\min}(E_FZ_{F,i}^rZ_{F,i}^r)$ is bounded away from zero for $F \in \mathcal{F}^{SR}_{P[r]}$. We
\[
\lambda_{\min}(E_FZ_F'Z_F') = \lambda_{\min}(E_F\Pi_{1F}^{-1/2}A_F'Z_iA_F\Pi_{1F}^{-1/2})
\]
\[
= \inf_{\lambda \in R^c:||\lambda||=1} [E_F(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i)^21(u_i^2 \leq c) + E_F(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i)^21(u_i^2 > c)]
\]
\[
\geq \inf_{\lambda \in R^c:||\lambda||=1} [c^{-1}E_F(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i)^2u_i^21(u_i^2 \leq c)]
\]
\[
= c^{-1}\inf_{\lambda \in R^c:||\lambda||=1} [E_F(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i)^2u_i^2 - E_F(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i)^2u_i^21(u_i^2 > c)]
\]
\[
\geq c^{-1}[\lambda_{\min}(\Pi_{1F}^{-1/2}A_F'\Omega_FA_F\Pi_{1F}^{-1/2}) - \sup_{\lambda \in R^c:||\lambda||=1} E_F(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i)^2u_i^21(u_i^2 > c)]
\]
\[
\geq c^{-1}[1 - E_F||\Pi_{1F}^{-1/2}A_F'Z_i||^2u_i^21(u_i^2 > c)]
\]
\[
\geq 1/(2c),
\]
(17.7)

where the second inequality uses \(g_i = Z_iu_i\) and \(\Omega_F := E_Fg_i'g_i\), the third inequality holds by \(\Pi_{1F}^{-1/2}A_F'\Omega_FA_F\Pi_{1F}^{-1/2} = I_F\) (using (3.4) and (3.5)) and by the Cauchy-Bunyakovsky-Schwarz inequality applied to \(\lambda'\Pi_{1F}^{-1/2}A_F'Z_i\), and the last inequality holds by the condition \(E_F||\Pi_{1F}^{-1/2}A_F'Z_i||^2u_i^2 \times 1(u_i^2 > c) \leq 1/2\) in \(\mathcal{F}^{SR}_{P(r)}\).

The moment bounds above and (17.7) establish that \(F \in \mathcal{F}^{SR}_{P[r]}\) implies that \(F \in \mathcal{F}_P\) for \(\delta \leq \min\{1, 1/(2c)\}\), when \(\mathcal{F}_P\) is defined with \((g_{F_i}'^*, G_{F_i}'^*)\) in place of \((g_i, G_i)\), where the definition of \(\mathcal{F}_P\) in (16.1) is taken to allow \(g_i\) and \(G_i\) to depend on \(F_i\). Now we apply Theorem 16.1 with \((g_{F_i}'^*, G_{F_i}'^*)\) and \(r\) in place of \((g_i, G_i)\) and \(k\) and \(\delta \leq \min\{1, 1/(2c)\}\) to obtain the correct asymptotic size and asymptotic similarity of the CQLR \(P\) test based on \((g_{F_i}'^*, G_{F_i}'^*)\) and \(r\) for the parameter space \(\mathcal{F}^{SR}_{P[r]}\) for \(r = 1, ..., k\). As noted above, the dependence of \(g_{F_i}'\) and \(G_{F_i}'\) on \(F_i\) does not cause a problem in the application of Theorem 16.1. This establishes the results of Theorem 15.2 for the SR-CQLR \(P\) test by the argument given above.\(^{49}\) The proof for the SR-CQLR \(P\) CS is essentially the same, but with \(\theta_0\) taking any value in \(\Theta\) and with \(\mathcal{F}^{SR}_{\Theta P}\) and \(\mathcal{F}_{\Theta 2}\), defined in (3.7) and just below (16.1), in place of \(\mathcal{F}^{SR}_{P}\) and \(\mathcal{F}_P\), respectively.

This completes the proof of Theorems 6.1 and 15.2 given Theorem 16.1.

\(^{49}\)We require \(\delta \leq \min\{1, 1/(2c)\}\), rather than \(\delta \leq 1/(2c)\), because \(\lambda_{\min}(E_Fg_{F_i}'g_{F_i}') = 1\) by (17.6) and \(\mathcal{F} \subset \mathcal{F}_{AR}\) requires \(\lambda_{\min}(E_Fg_{F_i}'g_{F_i}') \geq \delta\).

\(^{50}\)The fact that \(Z_{F_i}\) depends on \(\theta_0\) through \(\Pi_{1F}^{-1/2}(\theta_0)A_F(\theta_0)'\) and that \(G_{F_i}'(\theta_0) \neq (\partial/\partial \theta')g_{F_i}'(\theta_0)\) (because \((\partial/\partial \theta')Z_{F_i}\) is ignored in the specification of \(G_{F_i}'(\theta_0)\)) does not affect the application of Theorem 16.1. The reason is that the proof of this Theorem goes through even if \(Z_i\) depends on \(\theta_0\) and for any \(G_i(\theta_0)\) that satisfies the conditions in \(\mathcal{F}_P\), not just for \(G_i(\theta_0) := (\partial/\partial \theta')g_i(\theta_0)\).
18 Time Series Observations

In this section, we define the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests for observations that are strictly stationary strong mixing. We also generalize the asymptotic size results of Theorems 6.1 and 15.2 from i.i.d. observations to strictly stationary strong mixing observations. In the time series case, $F$ denotes the distribution of the stationary infinite sequence $\{W_i : i = \ldots, 0, 1, \ldots\}$.

We define

$$V_{F,n}(\theta) := Var_F \left( n^{-1/2} \sum_{i=1}^{n} \begin{pmatrix} g_i(\theta) \\ vec(G_i(\theta)) \end{pmatrix} \right),$$

$$\Omega_{F,n}(\theta) := Var_F \left( n^{-1/2} \sum_{i=1}^{n} g_i(\theta) \right), \text{ and } r_{F,n}(\theta) := r_k(\Omega_{F,n}(\theta)). \quad (18.1)$$

Note that $V_{F,n}(\theta)$, $\Omega_{F,n}(\theta)$, and $r_{F,n}(\theta)$ depend on $n$ in the time series case, but not in the i.i.d. case. We define $A_{F,n}(\theta)$ and $\Pi_{1F,n}(\theta)$ as $A_F(\theta)$ and $\Pi_{1F}(\theta)$ are defined in (3.4), (3.5), and the paragraph following (3.3), but with $\Omega_{F,n}(\theta)$ in place of $\Omega_F(\theta)$.

For the SR-AR test, the parameter space of time series distributions $F$ for the null hypothesis $H_0 : \theta = \theta_0$ is taken to be

$$\mathcal{F}_{TS,AR}^{SR} := \{ F : \{W_i : i = \ldots, 0, 1, \ldots\} \text{ are stationary and strong mixing under } F \}$$

strong mixing numbers $\{\alpha_F(m) : m \geq 1\}$ that satisfy $\alpha_F(m) \leq Cm^{-d},$

$$E_Fg_i = 0^k, \text{ and } \sup_{n \geq 1} E_F|\Pi_{1F,n}^{-1/2} A_{F,n}^i g_i|^2 \leq M \{18.2\}$$

for some $\gamma > 0$, $d > (2 + \gamma)/\gamma$, and $C, M < \infty$, where the dependence of $g_i$, $\Pi_{1F,n}$, and $A_{F,n}$ on $\theta_0$ is suppressed. For CS’s, we use the corresponding parameter space $\mathcal{F}_{TS,AR}^{SR}(\Theta, \theta_0) := \{ (F, \theta_0) : F \in \mathcal{F}_{TS,AR}^{SR}(\theta_0), F \in \mathcal{F}_{TS,AR}^{SR}(\theta_0) \}$. The moment conditions in $\mathcal{F}_{TS,AR}^{SR}$ are placed on the normalized moment functions $\Pi_{1F,n}^{-1/2} A_{F,n}^i g_i$ that satisfy $Var_F(n^{-1/2} \sum_{i=1}^{n} \Pi_{1F,n}^{-1/2} A_{F,n}^i g_i) = I_k$ for all $n \geq 1$.

For the SR-CQLR and SR-CQLR$_P$ tests, we use the null parameter spaces $\mathcal{F}_{TS}^{SR}$ and $\mathcal{F}_{TS,P}^{SR}$, respectively, which are defined as $\mathcal{F}_{TS}^{SR}$ and $\mathcal{F}_{TS,P}^{SR}$ are defined in (3.6) and (15.3), but with (i) $\mathcal{F}_{TS,AR}^{SR}$ in place of $\mathcal{F}_{TS,AR}^{SR}$, (ii) $A_F$ and $\Pi_{1F}$ replaced by $A_{F,n}$ and $\Pi_{1F,n}$, respectively, and (iii) $\sup_{n \geq 1}$ added before the quantities $\mathcal{F}_{TS}^{SR}$ and $\mathcal{F}_{TS,P}^{SR}$ that depend on $A_{F,n}$ and $\Pi_{1F,n}$. For SR-CQLR and SR-CQLR$_P$ CS’s, we use the parameter spaces $\mathcal{F}_{TS,\Theta}^{SR}$ and $\mathcal{F}_{TS,\Theta,P}^{SR}$, respectively, which are defined as $\mathcal{F}_{TS,\Theta,AR}^{SR}$

---

51 Asymptotics under drifting sequences of true distributions $\{F_n : n \geq 1\}$ are used to establish the correct asymptotic size of the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests and CS’s. Under such sequences, the observations form a triangular array of row-wise strictly stationary observations.
is defined, but with \( F_{TS}^{SR}(\theta_0) \) and \( F_{TS,P}^{SR}(\theta_0) \) in place of \( F_{TS,AR}^{SR}(\theta_0) \), where \( F_{TS}^{SR}(\theta_0) \) and \( F_{TS,P}^{SR}(\theta_0) \) denote \( F_{TS}^{SR} \) and \( F_{TS,P}^{SR} \) with their dependence on \( \theta_0 \) made explicit.

The SR-CQLR and SR-CQLR\(_P\) test statistics depend on some estimators \( \hat{V}_n \) (\( = \bar{V}_n(\theta_0) \)) of \( V_{F,n} \). The SR-AR test statistic only depends on an estimator \( \hat{\Omega}_n \) (\( = \bar{\Omega}_n(\theta_0) \)) of the submatrix \( \Omega_{F,n} \) of \( V_{F,n} \). For the SR-AR, SR-CQLR, and SR-CQLR\(_P\) tests, these estimators are heteroskedasticity and autocorrelation consistent (HAC) variance matrix estimators based on \( \{g_i - \bar{g}_n : i \leq n\} \), \( \{f_i - \hat{f}_n : i \leq n\} \) (defined in (5.3)), and \( \{u_i^* - \bar{u}_i^* \otimes Z_i : i \leq n\} \) (defined in (15.5)), respectively.

There are a number of HAC estimators available in the literature, e.g., see Newey and West (1987) and Andrews (1991).

We say that \( \hat{V}_n \) is **equivariant** if the replacement of \( g_i \) and \( G_i \) by \( A'g_i \) and \( A'G_i \), respectively, in the definition of \( \hat{V}_n \) transforms \( \hat{V}_n \) into \( (I_{p+1} \otimes A')\hat{V}_n(I_{p+1} \otimes A) \), for any matrix \( A \in \mathbb{R}^{r \times k} \) with full row rank \( r \leq k \) for any \( r = \{1, \ldots, k\} \). Equivariance of \( \hat{\Omega}_n \) means that the replacement of \( g_i \) by \( A'g_i \) transforms \( \hat{\Omega}_n \) into \( A'\hat{\Omega}_n A \). Equivariance holds quite generally for HAC estimators in the literature.

We write the \( (p+1)k \times (p+1)k \) matrix \( \hat{V}_n \) in terms of its \( k \times k \) submatrices:

\[
\hat{V}_n = \begin{bmatrix}
\hat{\Omega}_n & \hat{\Gamma}_{1n}' & \ldots & \hat{\Gamma}_{pn}' \\
\hat{\Gamma}_{1n} & \hat{\Omega}_{G1,n} & \ldots & \hat{\Omega}_{Gp+1,n} \\
\vdots & \vdots & \ddots & \vdots \\
\hat{\Gamma}_{pn} & \hat{\Omega}_{Gp+1,n} & \ldots & \hat{\Omega}_{Gpp,n}
\end{bmatrix}.
\] (18.3)

We define \( \bar{r}_n \) (\( = \bar{r}_n(\theta_0) \)) and \( \bar{A}_n \) (\( = \bar{A}_n(\theta_0) \)) as in (4.3) and (4.4) with \( \theta = \theta_0 \), but with \( \hat{\Omega}_n \) defined in (18.3), rather than in (4.1).

The asymptotic size and similarity properties of the tests considered here are the same for any consistent HAC estimator. Hence, for generality, we do not specify a particular estimator \( \hat{V}_n \) (or \( \hat{\Omega}_n \)). Rather, we state results that hold for any estimator \( \hat{V}_n \) (or \( \hat{\Omega}_n \)) that satisfies one the following assumptions when the null value \( \theta_0 \) is the true value. The following assumptions are used with the SR-CQLR test and CS, respectively.

**Assumption SR-V:**

(a) \( [I_{p+1} \otimes (\Pi_{F,n}^{-1/2}(\theta_0)A_{F,n}(\theta_0))] [\hat{V}_n(\theta_0) - V_{F,n}(\theta_0)] [I_{p+1} \otimes (A_{F,n}(\theta_0)\Pi_{F,n}^{-1/2}(\theta_0))] \rightarrow_{p} 0^{(p+1)k \times (p+1)k} \) under \( \{F_n : n \geq 1\} \) for any sequence \( \{F_n \in \mathcal{F}_{TS}^{SR} : n \geq 1\} \) for which \( V_{F,n}(\theta_0) \rightarrow V \) for some matrix \( V \) and \( r_{F,n}(\theta_0) = r \) for all \( n \) large, for any \( r = \{1, \ldots, k\} \).

(b) \( \hat{V}_n(\theta_0) \) is equivariant.

(c) \( \lambda g_i(\theta_0) = 0 \ \text{a.s.}[F] \) implies that \( \lambda \bar{\Omega}_n(\theta_0) \lambda = 0 \ \text{a.s.}[F] \) for all \( \lambda \in \mathbb{R}^k \) and \( F \in \mathcal{F}_{TS}^{SR} \).

For SR-CQLR CS’s, we use the following assumption that allows both the null parameter \( \theta_{0n} \),
as well as the distribution $F_n$, to drift with $n$.

**Assumption SR-V-CS:** $[I_{p+1} \otimes (\Pi_{1F_{n,n}}^{-1/2}(\theta_0n)A_{F_{n,n}}(\theta_0n))][\hat{V}_n(\theta_0n) - V_{F_{n,n}}(\theta_0n)][I_{p+1} \otimes (A_{F_{n,n}}(\theta_0n)\Pi_{1F_{n,n}}^{-1/2}(\theta_0n))] \to_p 0^{(p+1)k \times (p+1)k}$ under $\{F_n : n \geq 1\}$ for any sequence $\{(F_n, \theta_0n) \in \mathcal{F}_{T_S,\Theta}^{SR} : n \geq 1\}$ for which $V_{F_{n,n}}(\theta_0n) \to V$ for some matrix $V$ and $r_{F_{n,n}}(\theta_0n) = r$ for all $n$ large, for any $r \in \{1, \ldots, k\}$.

(b) $\hat{V}_n(\theta_0)$ is equivariant for all $\theta_0 \in \Theta$.

(c) $X'g_i(\theta_0) = 0$ a.s.$[F]$ implies that $X'\hat{\Omega}_n(\theta_0)\lambda = 0$ a.s.$[F]$ for all $\lambda \in R^k$ and $(F, \theta_0) \in \mathcal{F}_{T_S,\Theta}^{SR}$.

Assumptions SR-V(a) and SR-V-CS(a) require the HAC estimator based on the normalized moments and Jacobian (i.e., $\Pi_{1F_{n,n}}^{-1/2}(\theta_0n)A_{F_{n,n}}(\theta_0n)g_i(\theta_0n)$ and $\Pi_{1F_{n,n}}^{-1/2}(\theta_0n)A_{F_{n,n}}(\theta_0n)G_i(\theta_0n)$, respectively) to be consistent. This can be verified using standard methods. For typical HAC estimators, equvariance and Assumptions SR-V(c) and SR-V-CS(c) can be shown easily.

For the SR-CQLR$_P$ test and CS, we use **Assumptions SR-V$_P$** and **SR-V$_P$-CS**, which are defined as Assumptions SR-V and SR-V-CS are defined, respectively, but with $\mathcal{F}_{T_S,\Theta}^{SR}$ and $\mathcal{F}_{T_S,\Theta,P}^{SR}$ in place of $\mathcal{F}_{T_S}^{SR}$ and $\mathcal{F}_{T_S,\Theta}^{SR}$.

For the SR-AR test and CS, we use **Assumptions SR-\Omega** and **SR-\Omega-CS**, which are defined as Assumptions SR-V and SR-V-CS are defined, respectively, but with (i) Assumption SR-\Omega(a) being: $\Pi_{1F_{n,n}}^{-1/2}(\theta_0n)A_{F_{n,n}}(\theta_0n)[\hat{\Omega}_n(\theta_0) - \Omega_{F_{n,n}}(\theta_0n)]A_{F_{n,n}}(\theta_0n)\Pi_{1F_{n,n}}^{-1/2}(\theta_0n) \to_p 0^{k \times k}$ under $\{F_n : n \geq 1\}$ for any sequence $\{F_n \in \mathcal{F}_{T_S,\Theta,AR}^{SR} : n \geq 1\}$ for which $\Omega_{F_{n,n}}(\theta_0n) \to \Omega$ for some matrix $\Omega$ and $r_{F_{n,n}}(\theta_0n) = r$ for all $n$ large, for any $r \in \{1, \ldots, k\}$, (ii) Assumption SR-\Omega-CS(a) being as in (i), but with $\theta_0n$ and $\mathcal{F}_{T_S,\Theta,AR}^{SR}$ in place of $\theta_0$ and $\mathcal{F}_{T_S,\Theta,AR}^{SR}$, (iii) $\hat{\Omega}_n(\theta_0n)$ in place of $\hat{V}_n(\theta_0)$ in part (b) of each assumption, and (iv) $\mathcal{F}_{T_S,\Theta,AR}^{SR}$ in place of $\mathcal{F}_{T_S}^{SR}$ in part (c) of each assumption.

Now we define the SR-AR, SR-CQLR, and SR-CQLR$_P$ tests in the time series context. The definitions are the same as in the i.i.d. context given in Sections 3, 5 and 15 with the following changes. For all three tests, $\hat{\tau}_n$ and $\hat{A}_{n}^T$ in the condition $\hat{A}_{n}^{1/T \hat{\sigma}_{n}} \neq 0^{k-\hat{\tau}_n}$ in (4.7) are defined as in (4.3) and (4.4), but with $\hat{\Omega}_n$ defined to satisfy Assumption SR-\Omega, rather than being defined in (4.1). The SR-AR statistic is defined as in Section 4, but with $\hat{\Omega}_n$ defined to satisfy Assumption SR-\Omega. This affects the definitions of $\hat{\tau}_n$ and $\hat{A}_n$, given in (4.3) and (4.4). With these changes, the critical value for the SR-AR test in the time series case is defined in the same way as in the i.i.d. case.

In the time series case, the SR-QLR statistic is defined as in Section 5, but with $\hat{V}_n$ and $\hat{\Omega}_n$ defined to satisfy Assumption SR-V and (18.3) based on $\{f_i - \hat{f}_n : i \leq n\}$, in place of $\hat{V}_n$ and $\hat{\Omega}_n$ defined in (5.3) and (4.1), respectively. This affects the definitions of $\hat{R}_n$, $\hat{\Sigma}_n$, $\hat{L}_n$, $\hat{D}_n^*$, $\hat{\tau}_n$, $\hat{A}_n$, and $SR-AR_n$ (which appears in (5.7)). Given the previous changes, the definition of the SR-CQLR critical value is unchanged.
In the time series case, the SR-CQLR statistic is defined as in Section 15, but with \( \tilde{V}_n \) and \( \tilde{\Omega}_n \) defined to satisfy Assumption SR-V_P and (18.3) based on \( \{(u_i^* - \tilde{u}_i^*) \otimes Z_i : i \leq n\} \), rather than in (15.5) and (4.1), respectively. In turn, this affects the definitions of \( e_R^n, e_n, e_L^n, e_D^n, e_Q^n, b, A_n \), and \( SR-AR_n \). Given the changes described above, the definition of the SR-CQLR_P critical value is unchanged.

In the time series context,

\[
V_F := \lim_{n \to \infty} \text{Var}_F \left( n^{-1/2} \sum_{i=1}^{n} \begin{pmatrix} g_i \\ \text{vec}(G_i) \end{pmatrix} \right) = \sum_{m=-\infty}^{\infty} E_F \begin{pmatrix} g_i \\ \text{vec}(G_i - E_F G_i) \end{pmatrix}' \begin{pmatrix} g_i-m \\ \text{vec}(G_{i-m} - E_F G_{i-m}) \end{pmatrix},
\]

where the dependence of various quantities on the null value \( \theta_0 \) is suppressed for notational simplicity. The second equality holds for \( F \in \mathcal{F}_{TS,P}^{SR} \).

For the time series case, the asymptotic size and similarity results for the tests described above are as follows.

**Theorem 18.1** Suppose the SR-AR, SR-CQLR, and SR-CQLR_P tests are defined as in this section, the null parameter spaces for \( F \) are \( \mathcal{F}_{TS,AR}^{SR}, \mathcal{F}_{TS}^{SR}, \) and \( \mathcal{F}_{TS,P}^{SR} \), respectively, and the corresponding Assumption SR-\( \Omega \), SR-V, or SR-V_P holds for each test. Then, these tests have asymptotic sizes equal to their nominal size \( \alpha \in (0,1) \). These tests also are asymptotically similar (in a uniform sense) for the subsets of these parameter spaces that exclude distributions \( F \) under which \( g_i = 0 \) a.s. Analogous results hold for the SR-AR, SR-CQLR, and SR-CQLR_P CS’s for the parameter spaces \( \mathcal{F}_{TS,\Theta,AR}^{SR}, \mathcal{F}_{TS,\Theta}^{SR}, \) and \( \mathcal{F}_{TS,\Theta,P}^{SR} \), respectively, provided the corresponding Assumption SR-\( \Omega \)-CS, SR-V-CS, or SR-V_P-CS holds for each CS, rather than Assumption SR-\( \Omega \), SR-V, or SR-V_P.

19 SR-CQLR, SR-CQLR_P, and Kleibergen’s Nonlinear CLR Tests in the Homoskedastic Linear IV Model

It is desirable for tests to reduce asymptotically to Moreira’s (2003) CLR test in the homoskedastic linear IV regression model with fixed (i.e., nonrandom) IV’s when \( p = 1 \), where \( p \) is the number of endogenous rhs variables, which equals the dimension of \( \theta \). The reason is that the latter test has

\[\text{This is shown in the proof of Lemma 20.1 in Section 20 in the SM to AG1.}\]
been shown to have some (approximate) optimality properties under normality of the errors, see Andrews, Moreira, and Stock (2006, 2008) and Chernozhukov, Hansen, and Jansson (2009), and Andrews, Marmer, and Yu (2019).\footnote{Whether this also holds for $p \geq 2$ is an open question.}

In this section, we show that the components of the SR-QLR$_P$ statistic and its corresponding conditioning matrix are asymptotically equivalent to those of Moreira’s (2003) LR statistic and its conditioning statistic, respectively, in the homoskedastic linear IV model with $k \geq p$ fixed (i.e., nonrandom) IV’s and nonsingular moments variance matrix (whether or not the errors are Gaussian). This holds for all values of $p \geq 1$.

We also show that the same is true for the SR-QLR statistic and its conditioning matrix in some, but not in all cases (where the cases depend on the behavior of the reduced-form parameter matrix $\pi \in R^{k \times p}$ as $n \to \infty$.) Nevertheless, when $p = 1$, the SR-CQLR test and Moreira’s (2003) CLR test are asymptotically equivalent. When $p \geq 2$, for the cases where asymptotic equivalence of these tests does not hold, the difference is due only to the IV’s being fixed, whereas the SR-QLR statistic and its conditioning matrix are designed (essentially) for random IV’s.

We also evaluate the behavior of Kleibergen’s (2005, 2007) nonlinear CLR tests in the homoskedastic linear IV model with fixed IV’s. Kleibergen’s tests depend on the choice of a weight matrix for the conditioning statistic (which enters both the CLR test statistic and the critical value function). We find that when $p = 1$ Kleibergen’s CLR test statistic and conditioning statistic reduce asymptotically to those of Moreira (2003) when one employs the Jacobian-variance weighted conditioning statistic suggested by Kleibergen (2005, 2007) and Smith (2007). However, they do not when one employs the moments-variance weighted conditioning statistic suggested by Newey and Windmeijer (2009) and Guggenberger, Ramalho, and Smith (2012). Notably, the scale of the scalar conditioning statistic can differ from the desired value of one by a factor that can be arbitrarily close to zero or infinity (depending on the value of the reduced-form error matrix $\Sigma_Y$ and null hypothesis value $\theta_0$), see Lemma\footnote{Whether this also holds for $p \geq 2$ is an open question.} and Comment (iv) following it. Kleibergen’s nonlinear CLR tests depend on the form of a rank statistic. When $p \geq 2$, we find that no choice of rank statistic makes Kleibergen’s CLR test statistic and conditioning statistic reduce asymptotically to those of Moreira (2003) (when Jacobian- or moments-variance weighting is employed).

Section\footnote{Whether this also holds for $p \geq 2$ is an open question.} below provides finite-sample simulation results that illustrate the results of the previous paragraph for Kleibergen’s CLR test with moment-variance weighting.
19.1 Normal Linear IV Model with \( p \geq 1 \) Endogenous Variables

Here, we define the CLR test of Moreira (2003) in the homoskedastic Gaussian linear (HGL) IV model with \( p \geq 1 \) endogenous regressor variables and \( k \geq p \) fixed (i.e., nonrandom) IV’s. The linear IV regression model is

\[
y_{1i} = Y_{2i}'\theta + u_i \quad \text{and} \quad Y_{2i} = \pi'Z_i + V_{2i},
\]

(19.1)

where \( y_{1i} \in R \) and \( Y_{2i} \in R^p \) are endogenous variables, \( Z_i \in R^k \) for \( k \geq p \) is a vector of fixed IV’s, and \( \pi \in R^{k \times p} \) is an unknown unrestricted parameter matrix. In terms of its reduced-form equations, the model is

\[
y_{1i} = Z_i'\pi\theta + V_{1i}, \quad Y_{2i} = \pi'Z_i + V_{2i}, \quad V_i := (V_{1i}, V_{2i})', \quad V_{1i} = u_i + V_{2i}'\theta, \quad \text{and} \quad \Sigma_V := EV_iV_i'.
\]

(19.2)

For simplicity, no exogenous variables are included in the structural equation. The reduced-form errors are \( V_i \in R^{p+1} \). In the HGL model, \( V_i \sim N(0^{p+1}, \Sigma_V) \) for some positive definite \((p+1) \times (p+1)\) matrix \( \Sigma_V \).

The IV moment functions and their derivatives with respect to \( \theta \) are

\[
g(W_i, \theta) = Z_i(y_{1i} - Y_{2i}'\theta) \quad \text{and} \quad G(W_i, \theta) = -Z_iY_{2i}' \quad \text{where} \quad W_i := (y_{1i}, Y_{2i}, Z_i)'.
\]

(19.3)

Moreira (2003, p. 1033) shows that the LR statistic for testing \( H_0 : \theta = \theta_0 \) against \( H_1 : \theta \neq \theta_0 \) in the HGL model in (19.1)-(19.2) when \( \Sigma_V \) is known is

\[
LR_{HGL,n} := S_nT_n - \lambda_{\min}((S_n, T_n)', (S_n, T_n)), \quad \text{where}
\]

\[
S_n := (Z'_{n \times k}Z_{n \times k})^{-1/2}Z_{n \times k}Y_{0}(b_0'\Sigma_Vb_0)^{-1/2} = (n^{-1}Z'_{n \times k}Z_{n \times k})^{-1/2}n^{1/2}\hat{g}_n(b_0'\Sigma_Vb_0)^{-1/2} \in R^k,
\]

\[
T_n := (Z'_{n \times k}Z_{n \times k})^{-1/2}Z_{n \times k}Y_{0}(A_0'\Sigma_V^{-1}A_0)^{-1/2} - (n^{-1}Z'_{n \times k}Z_{n \times k})^{-1/2}n^{1/2}(\hat{G}_n\theta_0 - \hat{g}_n)(A_0'\Sigma_V^{-1}A_0)^{-1/2} \in R^{k \times p},
\]

\[
Z_{n \times k} := (Z_1, ..., Z_n)' \in R^{n \times k}, \quad Y := (Y_1, ..., Y_n)' \in R^{n \times (p+1)}, \quad Y_i := (y_{1i}, Y_{2i})' \in R^{p+1},
\]

\[
b_0 := (1, -\theta_0)' \in R^{p+1}, \quad \hat{g}_n := n^{-1}\sum_{i=1}^n g(W_i, \theta_0), \quad A_0 := (\theta_0, I_p)' \in R^{(p+1) \times p}, \quad \hat{G}_n := n^{-1}\sum_{i=1}^n G(W_i, \theta_0),
\]

(19.4)
\( \lambda_{\min}(\cdot) \) denotes the smallest eigenvalue of a matrix, and the second equality for \( T_n \) holds by (29.12) in the SM. Note that \((S_n, T_n)\) is a (conveniently transformed) sufficient statistic for \((\theta, \pi)\) under normality of \(V_i\), known variance matrix \(\Sigma_V\), and fixed IV’s.

Moreira’s (2003) CLR test uses the \( LR_{HGL,n} \) statistic and a conditional critical value that depends on the \( k \times p \) matrix \( T_n \) through the conditional critical value function \( c_{k,p}(\cdot, 1 - \alpha) \) defined in (5.8). For \( \alpha \in (0,1) \), Moreira’s CLR test with nominal level \( \alpha \) rejects \( H_0 \) if

\[
LR_{HGL,n} > c_{k,p}(T_n, 1 - \alpha) . 
\]

When \( \Sigma_V \) is unknown, Moreira (2003) replaces \( \Sigma_V \) by a consistent estimator.

Moreira’s (2003) CLR test is similar with finite-sample size \( \alpha \) in the HGL model with known \( \Sigma_V \). Intuitively, the strength of the IV’s affects the null distribution of the test statistic \( LR_{HGL,n} \) and the critical value \( c_{k,p}(T_n, 1 - \alpha) \) adjusts accordingly to yield a test with size \( \alpha \) using the dependence of the null distribution of \( T_n \) on the strength of the IV’s. When \( p = 1 \), this test has been shown to have some (approximate) asymptotic optimality properties, see Andrews, Moreira, and Stock (2006, 2008), Chernozhukov, Hansen, and Jansson (2009), and Andrews, Marmer, and Yu (2019).

For \( p \geq 2 \), the asymptotic properties of Moreira’s CLR test, such as its asymptotic size and similarity, are not available in the literature. The results for the SR-CQLR\(_P\) test, specialized to the linear IV model (with or without Gaussianity, homoskedasticity, and/or independence of the errors), fill this gap.

### 19.2 Homoskedastic Linear IV Model

The model we consider in the remainder of this section is the homoskedastic linear IV model introduced in Section 19.1 but without the assumption of normality of the reduced-form errors \( V_i \). Specifically, we use the following assumption.

**Assumption HLIV:** (a) \( \{V_i \in \mathbb{R}^{p+1} : i \geq 1\} \) are i.i.d., \( \{Z_i \in \mathbb{R}^{k} : i \geq 1\} \) are fixed, not random, and \( k \geq p \).

(b) \( EV_i = 0 \), \( \Sigma_V := EV_iV_i' \) is pd, and \( E||V_i||^4 < \infty \).

(c) \( n^{-1} \sum_{i=1}^{n} Z_iZ_i' \rightarrow K_Z \) for some pd matrix \( K_Z \in \mathbb{R}^{k \times k} \), \( n^{-1} \sum_{i=1}^{n} ||Z_i||^6 = o(n) \), and \( \sup_{c \leq n}(c'dZ_i)^2/\sum_{i=1}^{n}(c'dZ_i)^2 \rightarrow 0 \forall c \neq 0^k \).

(d) \( \sup_{\pi \in \Pi} ||\pi|| < \infty \), where \( \Pi \) is the parameter space for \( \pi \).

\(^{54}\) We let \( Z_{n \times k} \) (rather than \( Z \)) denote \( (Z_1, \ldots, Z_n)' \), because we use \( Z \) to denote a \( k \) vector of standard normals below.

\(^{55}\) In this section, the underlying i.i.d. random variables \( \{V_i : i \geq 1\} \) have a distribution that does not depend on \( n \). Hence, for notational simplicity, we denote expectations by \( E \), rather than \( E_{F_n} \). Nevertheless, it should be kept in mind that the reduced-form parameters \( \pi_n \) may depend on \( n \).
(e) \( \lambda_{\text{max}}(\Sigma_V)/\lambda_{\text{min}}(\Sigma_V) \leq 1/\varepsilon \) for \( \varepsilon > 0 \) as in the definition of the SR-QLR or SR-QLR\(_P\) statistic.

Here HLIV abbreviates “homoskedastic linear IV model.” Assumption HLIV(b) specifies that the reduced-form errors are homoskedastic (because their variance matrix does not depend on \( i \) or \( Z_i \)). Assumptions HLIV(c) and (d) are used to obtain a weak law of large numbers (WLLN) and central limit theorem (CLT) for certain quantities under drifting sequences of reduced-form parameters \( \{\pi_n : n \geq 1\} \). These assumptions are not very restrictive. Note that Assumptions HLIV(a)-(c) imply that the variance matrix of the sample moments is pd. This implies that \( \bar{r}_n (= \bar{r}_n(\theta_0)) = k \) wp→1 (by Lemma 19.1(b) below) and no SR adjustment of the SR-CQLR tests occurs (wp→1). Assumption HLIV(e) guarantees that the eigenvalue adjustment used in the definition of the SR-QLR statistics does not have any effect asymptotically. One could analyze the properties of the SR-CQLR tests when this condition is eliminated. One would still obtain asymptotic null rejection probabilities equal to \( \alpha \), but the eigenvalue adjustment would render the SR-CQLR tests to behave somewhat differently than Moreira’s CLR test, because the latter test does not employ an eigenvalue adjustment.

19.3 SR-CQLR\(_P\) Test

The components of the SR-QLR\(_P\) statistic and its conditioning matrix are \( n^{1/2}\hat{\Omega}_n^{-1/2}g_n \) and \( n^{1/2}\hat{D}_n^* \) (see (4.2) and (15.6)) when \( \hat{r}_n = k \), which holds wp→1 under Assumption HLIV. Those of Moreira (2003) are \( \bar{S}_n \) and \( \bar{T}_n \) (see (19.4)). The asymptotic equivalence of these components in the model specified by (19.1)-(19.2) and Assumption HLIV is established in parts (e) and (f) of the following lemma. Parts (a)-(d) of the lemma establish the asymptotic behavior of the components \( \hat{\Omega}_n \) and \( \hat{\Sigma}_n \) of the test statistic SR-QLR\(_Pn\) and its conditioning statistic.

**Lemma 19.1** Suppose Assumption HLIV holds. Under the null hypothesis \( H_0 : \theta = \theta_0 \), for any sequence of reduced-form parameters \( \{\pi_n \in \Pi : n \geq 1\} \) and any \( p \geq 1 \), we have

(a) \( \bar{R}_n \to_p \Sigma_V \otimes K_Z \),
(b) \( \hat{\Omega}_n \to_p (b_0'\Sigma_V b_0)K_Z \), where \( b_0 := (1, -\theta_0')' \),
(c) \( \bar{\Sigma}_n \to_p (b_0'\Sigma_V b_0)^{-1}\Sigma_V \),
(d) \( \hat{\Sigma}_n \to_p (b_0'\Sigma_V b_0)^{-1}\Sigma_V \),
(e) \( n^{1/2}\hat{\Omega}_n^{-1/2}\hat{g}_n = \bar{S}_n + o_p(1) \), and
(f) \( n^{1/2}\hat{D}_n^* = -(I_k + o_p(1))\bar{T}_n(I_p + o_p(1)) + o_p(1) \).

**Comments:** (i) The minus sign in Lemma 19.1(f) is not important because QLR\(_Pn\) (defined in the paragraph containing (15.7) using the formula in (5.7)) is unchanged if \( \hat{D}_n^* \) is replaced by \( -\hat{D}_n^* \).
(and \(SR-QLR_{P_n} = QLR_{P_n} \) wp→1 under Assumption HLIV)\(^{56}\)

(ii) The results of Lemma 19.1 hold under the null hypothesis. Statistics that differ by \(o_p(1)\) under sequences of null distributions also differ by \(o_p(1)\) under sequences of contiguous alternatives. Hence, the asymptotic equivalence results of Lemma 19.1(e) and (f) also hold under contiguous alternatives to the null.

Note that in the linear IV regression model the alternative parameter values \(\{\theta_n : n \geq 1\}\) that yield contiguous sequences of distributions from a sequence of null distributions depend on the strength of identification as measured by \(\pi_n\). The reduced-form equation (19.2) states that \(y_{1i} = Z_i'\pi_n\theta_n + V_{1i}\) when \(\pi_n\) and \(\theta_n\) are the true values of \(\pi\) and \(\theta\). Contiguous alternatives to the null distributions with parameters \(\pi_n\) and \(\theta_n\) are obtained for parameter values \(\pi_n\) and \(\theta_n(\neq \theta_0)\) that satisfy \(\pi_n\theta_n - \pi_n\theta_0 = \pi_n(\theta_n - \theta_0) = O(n^{-1/2})\). If the IV’s are strong, i.e., \(\lim \inf_{n \rightarrow \infty} \pi_n'\pi_n^{-1} \sum_{i=1}^n Z_i'Z_i\pi_n > 0\), then contiguous alternatives have true \(\theta_n\) values of distance \(O(n^{-1/2})\) from the null value \(\theta_0\). If the IV’s are weak in the standard sense, e.g., \(\pi_n = \pi n^{-1/2}\) for some fixed matrix \(\pi\), then all \(\theta\) values not equal \(\theta_0\) yield contiguous alternatives. For semi-strong identification in the standard sense, e.g., \(\pi_n = \pi n^{-\delta}\) for some \(\delta \in (0, 1/2)\) and some fixed full-column-rank matrix \(\pi\), the contiguous alternatives have \(\theta_n - \theta_0 = O(n^{-(1/2-\delta)})\). For joint weak identification, contiguity occurs when \(\pi_n = (\pi_{1n}, \ldots, \pi_{pn}) \in R^{k \times p}, n^{1/2}||\pi_{jn}|| \rightarrow \infty\) for all \(j \leq p\), \(\lim_{n \rightarrow \infty} \lambda_{\text{min}}(n\pi_n'\pi_n) < \infty\), and \(\theta_n\) is such that \(\pi_n(\theta_n - \theta_0) = O(n^{-1/2})\).

(iii) The proofs of Lemma 19.1 and Lemmas 19.2 and 19.3 below are given in Section 29 below.

19.4 SR-CQLR Test

The components of the SR-QLR statistic and its conditioning matrix are \(n^{1/2}\hat{\Omega}_n^{-1/2}g_n\) and \(n^{1/2}\hat{D}_n^*\) (see (4.1) and (5.7)) when \(\hat{\tau}_n = k\), which holds wp→1 under Assumption HLIV. Here we show that the conditioning statistic \(n^{1/2}\hat{D}_n^*\) is asymptotically equivalent to Moreira’s (2003) conditioning statistic \(\bar{T}_n\) (in the homoskedastic linear IV model with fixed IV’s) when \(\pi_n \rightarrow 0^{k \times p}\). This includes the cases of standard weak identification and semi-strong identification. It is not asymptotically equivalent in other circumstances. (See Comment (ii) to Lemma 19.2 below.) Nevertheless, under strong and semi-strong IV’s, the SR-CQLR test and Moreira’s CLR test are asymptotically equivalent.\(^{57}\) In consequence, when \(p = 1\), the SR-CQLR test and Moreira’s CLR test are asymptotically equivalent.\(^{57}\) This holds because, under strong and semi-strong IV’s, the SR-QLR statistic and Moreira’s CLR statistic behave asymptotically like LM statistics that project onto \(n^{1/2}\hat{\Omega}_n^{-1/2}D_n\) (or equivalently, \(n^{1/2}\hat{\Omega}_n^{-1/2}D_n\hat{L}_n^{-1/2}\)) and \(\bar{T}_n\), respectively, see Theorem 7.1 for the SR-QLR statistic, and \(n^{1/2}\hat{\Omega}_n^{-1/2}D_n\hat{L}_n^{-1/2}\) and \(\bar{T}_n\) are asymptotically equivalent (up to multiplication by −1) by Lemma 19.1(f). Furthermore, the conditional critical values of the two tests both converge.
totically equivalent (because standard weak, strong, and semi-strong identification cover all possible cases). When \( p \geq 2 \), this is not true (because weak identification can occur even when \( \pi_n \to 0^{k \times p} \), if \( n^{1/2} \) times the smallest singular value of \( \pi_n \) is \( O(1) \)). Although asymptotic equivalence of the tests fails in some cases when \( p \geq 2 \), the differences appear to be small because they are due only to the differences between fixed IV’s and random IV’s (which cause \( \Sigma_V \) to differ somewhat from \( \Sigma_{V*} \) defined below).

For \( \pi \in R^{k \times p} \), define

\[
\zeta_n(\pi) := n^{-1} \sum_{i=1}^{n} (\pi' \otimes Z_i) Z_i' (\pi' \otimes Z_i) - \left( n^{-1} \sum_{i=1}^{n} (\pi' \otimes Z_i) Z_i \right) \left( n^{-1} \sum_{i=1}^{n} (\pi' \otimes Z_i) Z_i \right)' \in R^{kp \times kp}.
\]  

(19.6)

If \( \lim n^{-1} \sum_{i=1}^{n} vec(Z_i Z_i') vec(Z_i Z_i)' \) exists, then \( \zeta(\pi) := \lim \zeta_n(\pi) \) exists for all \( \pi \in R^{k \times p} \). Define

\[
R(\pi) := \Sigma_V \otimes K_Z + (B' \otimes I_k) \begin{bmatrix} 0^{k \times k} & 0^{k \times kp} \\ 0^{kp \times k} & \zeta(\pi) \end{bmatrix} (B \otimes I_k) \in R^{(p+1) \times (p+1)},
\]  

(19.7)

where \( B = B(\theta_0) \) is defined in [5.3].

The probability limit of \( \Sigma_n \) is shown below to be the symmetric matrix \( (b_0^T \Sigma_V b_0)^{-1} \Sigma_{V*} \in R^{(p+1) \times (p+1)} \), where \( \Sigma_{V*} \) is defined as follows. The \((j, \ell)\) element of \( \Sigma_{V*} \) is

\[
\Sigma_{V* j \ell} := tr(R_{j \ell}(\pi*)' K_Z^{-1})/k,
\]  

(19.8)

where \( R_{j \ell}(\pi*) \) denotes the \((j, \ell)\) \( k \times k \) submatrix of \( R(\pi*) \) for \( j, \ell = 1, ..., p+1 \) and \( \pi* = \lim \pi_n \). Equivalently, \( \Sigma_{V*} \) is the unique minimizer of \( \| [I_{p+1} \otimes ((b_0^T \Sigma_V b_0)^{-1/2} K_Z^{-1/2})] [\Sigma \otimes K_Z - R(\pi*)] [I_{p+1} \otimes ((b_0^T \Sigma_V b_0)^{-1/2} K_Z^{-1/2})] \| \) over all symmetric pd matrices \( \Sigma \in R^{(p+1) \times (p+1)} \). Note that when \( \zeta(\pi*) = 0 \) (as occurs when \( \pi* = 0^{k \times p} \)), \( \Sigma_{V*} = \Sigma_V \) (because \( R(\pi*) = \Sigma_V \otimes K_Z \) in this case).

We use the following assumption.

**Assumption HLIV2**: (a) \( \lim n^{-1} \sum_{i=1}^{n} vec(Z_i Z'_i) vec(Z_i Z'_i)' \) exists and is finite,

(b) \( \pi_n \to \pi* \) for some \( \pi* \in R^{k \times p} \), and

(c) \( \lambda_{max}(\Sigma_{V*})/\lambda_{min}(\Sigma_{V*}) \leq 1/\varepsilon \) for \( \varepsilon > 0 \) as in the definition of the SR-QLR statistic.

Assumption HLIV2(c) implies that the eigenvalue adjustment to \( \Sigma_n \) employed in the SR-QLR statistic has no effect asymptotically. One could analyze the behavior of the SR-CQLR test when this condition is eliminated. This would not affect the asymptotic null rejection probabilities, but it would affect the form of the asymptotic distribution when the condition is violated. For brevity, in probability to \( \chi^2_{p,1-\alpha} \) under strong and semi-strong identification, see Theorem 7.1 for the SR-CQLR critical value.
we do not do so here.

The asymptotic behavior of \( n^{1/2} \hat{D}_n^* \) is given in the following lemma. Under Assumption HLIV, \( n^{1/2} \hat{D}_n^* \) equals the SR-CQLR conditioning statistic \( n^{1/2} \hat{D}_{An}^* \) \( \text{wp} \rightarrow 1 \) (because \( \hat{r}_n = k \text{ wp} \rightarrow 1 \)).

**Lemma 19.2** Suppose Assumptions HLIV and HLIV2 hold. Under the null hypothesis \( H_0 : \theta = \theta_0 \) and any \( p \geq 1 \), we have

(a) \( \hat{R}_n \rightarrow_p R(\pi_*) \),

(b) \( \hat{\Sigma}_n \rightarrow_p (b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V*} \),

(c) \( \hat{\Sigma}^e_n \rightarrow_p (b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V*} \), and

(d) \( n^{1/2} \hat{D}_n^* = -(I_k + o_p(1)) \hat{T}_n (L_{V0}^{-1/2} L_{V*}^{1/2} + o_p(1)) + o_p(1) \), where \( L_{V0} := (\theta_0, I_p) \Sigma_V^{-1} (\theta_0, I_p)' \in R^{p \times p} \) and \( L_{V*} := (\theta_0, I_p) \Sigma_{V*}^{-1} (\theta_0, I_p)' \in R^{p \times p} \).

**Comments:** (i) If \( \pi_* = 0^{k \times p} \), which occurs when all \( \theta \) parameters are either weakly identified in the standard sense or semi-strongly identified, then \( \zeta(\pi_*) = 0^{kp \times kp} \), \( R(\pi_*) = \Sigma_V \otimes K_Z \), and \( \Sigma_{V*} = \Sigma_V \). In this case, Lemma 19.2(d) yields

\[
n^{1/2} \hat{D}_n^* = -(I_k + o_p(1)) \hat{T}_n (I_p + o_p(1) + o_p(1) \tag{19.9}\]

and \( n^{1/2} \hat{D}_n^* \) is asymptotically equivalent to \( \hat{T}_n \) (up to multiplication by \(-1\)).

(ii) On the other hand, if \( \pi_* \neq 0^{k \times p} \), then \( n^{1/2} \hat{D}_n^* \) is not asymptotically equivalent to \( \hat{T}_n \) in general due to the \( \zeta(\pi_*) \) factor that appears in the second summand of \( R(\pi_*) \) in (19.7). This factor arises because the IV’s are fixed in the linear IV model (by assumption), but the variance estimator \( \hat{V}_n \), which appears in \( \hat{R}_n \), see (5.3), and which determines \( \hat{\Sigma}_n \) and \( \Sigma_{V*} \), treats the IV’s as though they are random.

19.5 Kleibergen’s Nonlinear CLR Tests

19.5.1 Definitions of the Tests

This section analyzes the behavior of Kleibergen’s (2005, 2007) nonlinear CLR tests in the homoskedastic linear IV regression model with \( k \geq p \) fixed IV’s. The behavior of Kleibergen’s nonlinear CLR tests is found to depend on the choice of weighting matrix for the conditioning statistic. We find that when \( p = 1 \) (where \( p \) is the dimension of \( \theta \)) and one employs the Jacobian-variance weighted conditioning statistic, Kleibergen’s CLR test and conditioning statistics reduce asymptotically to those of Moreira’s (2003) CLR test, as desired. This type of weighting has been suggested by Kleibergen’s (2005, 2007) and Smith (2007). On the other hand, Kleibergen’s CLR test and conditioning statistics do not reduce asymptotically to those of Moreira (2003) when \( p = 1 \) and
one employs the moments-variance weighted conditioning statistic. The latter has been suggested by Newey and Windmeijer (2009) and Guggenberger, Ramalho, and Smith (2012). Furthermore, the scale of the scalar conditioning statistic can differ from the desired value of one by a factor that can be arbitrarily close to zero or infinity (depending on the value of the reduced-form error matrix $\Sigma_V$ and null hypothesis value $\theta_0$). This has adverse effects on the power of the moment-variance weighted CLR test.

When $p \geq 2$, Kleibergen’s nonlinear CLR tests depend on the form of a rank statistic. In this case, we find that no choice of rank statistic makes Kleibergen’s CLR test statistic and conditioning statistic reduce asymptotically to those of Moreira (2003).

Kleibergen’s test statistic takes the form:

$$CLR_n(\theta) := \frac{1}{2} \left( AR_n(\theta) - rk_n(\theta) + \sqrt{(AR_n(\theta) - rk_n(\theta))^2 + 4LM_n(\theta) \cdot rk_n(\theta)} \right),$$

(19.10)

and $rk_n(\theta)$ is a real-valued rank statistic, which is a conditioning statistic (i.e., the critical value may depend on $rk_n(\theta)$).

The critical value of Kleibergen’s CLR test is $c(1 - \alpha, rk_n(\theta))$, where $c(1 - \alpha, r)$ is the $1 - \alpha$ quantile of the distribution of

$$clr(r) := \frac{1}{2} \left( \chi^2_p + \chi^2_{k-p} - r + \sqrt{(\chi^2_p + \chi^2_{k-p} - r)^2 + 4\chi^2_p r^2} \right)$$

(19.11)

for $0 \leq r < \infty$ and the chi-square random variables $\chi^2_p$ and $\chi^2_{k-p}$ in (19.11) are independent. The CLR test rejects the null hypothesis $H_0: \theta = \theta_0$ if $CLR_n > c(1 - \alpha, rk_n)$ (where, as elsewhere, the dependence of these statistics on $\theta_0$ is suppressed for simplicity).

Kleibergen’s CLR test depends on the choice of the rank statistic $rk_n(\theta)$. Kleibergen (2005, p. 1114, 2007, eq. (37)) and Smith (2007, p. 7, footnote 4) propose to take $rk_n(\theta)$ to be a function of $\tilde{V}_{Dn}^{-1/2}(\theta)vec(\tilde{D}_n(\theta))$, where $\tilde{V}_{Dn}(\theta) \in R^{kp \times kp}$ is a consistent estimator of the covariance matrix of the asymptotic distribution of $vec(\tilde{D}_n(\theta))$ (after suitable normalization). We refer to $\tilde{V}_{Dn}^{-1/2}(\theta)vec(\tilde{D}_n(\theta))$ as the orthogonalized sample Jacobian with Jacobian-variance weighting. In the i.i.d. case considered here, we have

$$\tilde{V}_{Dn}(\theta) := n^{-1} \sum_{i=1}^{n} vec(G_i(\theta) - \tilde{G}_n(\theta))vec(G_i(\theta) - \tilde{G}_n(\theta))' - \tilde{\Gamma}_n(\theta)\tilde{\Omega}_n^{-1}(\theta)\tilde{\Gamma}_n(\theta)',$$

(19.12)

$$\tilde{\Gamma}_n(\theta) := (\tilde{\Gamma}_{n1}(\theta)', \ldots, \tilde{\Gamma}_{nk}(\theta)')' \in R^{kp \times k}.$$
and $\hat{\Gamma}_{1n}(\theta),...,\hat{\Gamma}_{pn}(\theta)$ are defined in \[5.2\].

Newey and Windmeijer (2009) and Guggenberger, Ramalho, and Smith (2012) propose to take $rk_n(\theta)$ to be a function of $\hat{\Omega}_n^{-1/2}(\theta)\hat{D}_n(\theta)$. We refer to $\hat{\Omega}_n^{-1/2}(\theta)\hat{D}_n(\theta)$ as the orthogonalized sample Jacobian with moment-variance weighting. Below we consider both choices. For reasons that will become apparent, we treat the cases $p = 1$ and $p \geq 2$ separately.

19.5.2 $p = 1$ Case

Whether Kleibergen’s nonlinear CLR test reduces asymptotically to Moreira’s CLR test in the homoskedastic linear IV regression model depends on the rank statistic chosen. Here we consider the two choices of rank statistic that have been considered in the literature. We find that Kleibergen’s nonlinear CLR test reduces asymptotically to Moreira’s CLR test with a rank statistic based on $\hat{V}_{Dn}(\theta)$, but not with a rank statistic based on $\hat{\Omega}_n(\theta)$. This illustrates that the flexibility in the choice of the rank statistic for Kleibergen’s CLR test can have drawbacks. It may lead to a test that has reduced power.

When $p = 1$, some calculations (based on the closed-form expression for the minimum eigenvalue of a $2 \times 2$ matrix) show that

$$CLR_n(\theta) = AR_n(\theta) - \lambda_{\min}((n^{1/2}\hat{\Omega}_n^{-1/2}(\theta)\hat{g}_n(\theta), r_n(\theta))'((n^{1/2}\hat{\Omega}_n^{-1/2}(\theta)\hat{g}_n(\theta), r_n(\theta)))$$

provided

$$rk_n(\theta) = r_n(\theta)'r_n(\theta)$$

for some random vector $r_n(\theta) \in \mathbb{R}^k$. \hspace{1cm} (19.13)

This equivalence is the origin of the $p = 1$ formula for the LR statistic in Moreira (2003). Hence, when $p = 1$, for testing $H_0 : \theta = \theta_0$, Kleibergen’s test statistic with $rk_n(\theta) = r_n(\theta)'r_n(\theta)$ is of the same form as Moreira’s (2003) LR statistic with $r_n(\theta_0)$ in place of $\overline{T}_n$ and with $n^{1/2}\hat{\Omega}_n^{-1/2}(\theta_0)\hat{g}_n(\theta_0)$ in place of $\overline{S}_n$, where $\theta_0$ is the null value of $\theta$.\hspace{1cm} (19.14)

The two choices for $rk_n(\theta)$ that we consider when $p = 1$ are

$$rk_{1n}(\theta) := n\hat{D}_n(\theta)'\hat{V}_{Dn}^{-1}(\theta)\hat{D}_n(\theta)$$

and

$$rk_{2n}(\theta) := n\hat{D}_n(\theta)'\hat{\Omega}_n^{-1}(\theta)\hat{D}_n(\theta).$$

The statistic $rk_{1n}(\theta)$ has been proposed by Kleibergen (2005, 2007) and Smith (2007) and $rk_{2n}(\theta)$ has been proposed by Newey and Windmeijer (2009) and Guggenberger, Ramalho, and Smith (2012).

Let

$$\zeta_n(\pi) := n^{-1}\sum_{i=1}^n Z_iZ_i'Z_i'\pi^2 - \left(n^{-1}\sum_{i=1}^n Z_iZ_i'\pi\right)'\left(n^{-1}\sum_{\ell=1}^n Z_\ell Z_\ell'\pi\right).$$

(19.15)

\footnote{The functional form of the rank statistics that have been considered in the literature, such as the statistics of Cragg and Donald (1996, 1997), Robin and Smith (2000), and Kleibergen and Paap (2006) all reduce to the same function when $p = 1$. Specifically, $rk_n(\theta)$ equals the squared length of some $k$ vector $r_n(\theta)$.}
This definition of $\zeta_n(\pi)$ is the same as in (19.6) when $p = 1$.

**Lemma 19.3** Suppose Assumption HLIV holds and $p = 1$. Under the null hypothesis $H_0 : \theta = \theta_0$, for any sequence of reduced-form parameters $\{\pi_n : n \geq 1\}$, we have

(a) $r_k(\theta_0) = T_n^\prime[I_k + L_{V_0}K^1/2_n\zeta_n(\pi_n)K^1/2_z + o_p(1)]^{-1}T_n \cdot (1 + o_p(1)) + o_p(1)$,

(b) $r_k(\theta_0) = T_n^\prime T_n(L_{V_0}b_0^\prime \Sigma_{V_0}b_0)^{-1} \cdot (1 + o_p(1)) + o_p(1)$, where $L_{V_0} := (\theta_0, 1)^{-1}(\theta_0, 1)' \in R$, and

(c) $L_{V_0}b_0^\prime \Sigma_{V_0}b_0 = \frac{(1-2\theta_0\rho+\theta_0^2c^2)^2}{c^2(1-\rho^2)}$, where $c = \text{Var}(V_{2i})/\text{Var}(V_{1i}) > 0$ and $\rho = \text{Corr}(V_{1i}, V_{2i}) \in (-1, 1)$.

**Comments:** (i) If $\pi_n \to 0$, then $\zeta_n(\pi_n) \to 0$ and Lemma 19.3(a) shows that $r_k(\theta_0)$ equals $T_n^\prime T_n(1 + o_p(1)) + o_p(1)$. That is, under weak IV’s and semi-strong IV’s, $r_k(\theta_0)$ reduces asymptotically to Moreira’s (2003) conditioning statistic. Under strong IV’s, this does not occur. However, under strong IV’s, we have $r_k(\theta_0) \to_\rho \infty$, just as $T_n^\prime T_n \to_\rho \infty$. In consequence, the test constructed using $r_k(\theta_0)$ has the same asymptotic properties as Moreira’s (2003) CLR test under the null and contiguous alternative distributions.

(ii) Simple calculations show that $\zeta_n(\pi_n)$ is positive semi-definite (psd). Hence, $r_k(\theta_0)$ is smaller than it would be if the second summand in the square brackets in Lemma 19.3(a) was zero.

(iii) Lemma 19.3(b) shows that the rank statistic $r_k(\theta_0)$ differs asymptotically from Moreira’s conditioning statistic $T_n^\prime T_n$ by the scale factor $(L_{V_0}b_0^\prime \Sigma_{V_0}b_0)^{-1}$. Thus, the nonlinear CLR test considered by Newey and Windmeijer (2009) and Guggenberger, Ramalho, and Smith (2012) does not reduce asymptotically to Moreira’s (2003) CLR test in the homoskedastic linear IV regression model with fixed IV’s under weak IV’s. This has negative consequences for its power. Under strong or semi-strong IV’s, this test does reduce asymptotically to Moreira’s (2003) CLR test because $r_k(\theta_0) \to_\rho \infty$, just as $T_n^\prime T_n \to_\rho \infty$, which is sufficient for asymptotic equivalence in these case.

(iv) For example, if $\rho = 0$ and $c = 1$ in Lemma 19.3(c), then $(L_{V_0}b_0^\prime \Sigma_{V_0}b_0)^{-1} = (1+\theta_0^2)^{-2} \leq 1$. In this case, if $|\theta_0| = 1$, then $(L_{V_0}b_0^\prime \Sigma_{V_0}b_0)^{-1} = 1/4$ and $r_k(\theta_0) = 1/4$ as large as $T_n^\prime T_n$ asymptotically. On the other hand, if $\rho = 0$ and $\theta_0 = 0$, then $(L_{V_0}b_0^\prime \Sigma_{V_0}b_0)^{-1} = c^2$, which can be arbitrarily close to zero or infinity depending on $c$.

(v) When $(L_{V_0}b_0^\prime \Sigma_{V_0}b_0)^{-1}$ is large (small), the $r_k(\theta_0)$ statistic is larger (smaller) than desired and it behaves as though the IV’s are stronger (weaker) than they really are, which sacrifices power unless the IV’s are quite strong (weak). Note that the inappropriate scale of $r_k(\theta_0)$ does not cause asymptotic size problems, only power reductions.
19.5.3  $p \geq 2$ Case

When $p \geq 2$, Kleibergen’s (2005) nonlinear CLR test does not reduce asymptotically to Moreira’s (2003) CLR test for any choice of rank statistic $rk_n(\theta_0)$ for several reasons.

First, Moreira’s (2003) LR statistic is given in (19.4), whereas Kleibergen’s (2005) nonlinear LR statistic is defined in (19.10). By Lemma 19.1(e), $n^{1/2}\hat{\Omega}_n^{-1/2}\hat{g}_n = \mathcal{S}_n + o_p(1)$, where, here and below, we suppress the dependence of various quantities on $\theta_0$. Hence, $AR_n = \mathcal{S}_n^T\mathcal{S}_n + o_p(1)$. Even if $rk_n$ takes the form $r'_n r_n$ for some random $k$ vector $r_n$, it is not the case that

$$CLR_n = AR_n - \lambda_{\min}(n^{1/2}\hat{\Omega}_n^{-1/2}\hat{r}_n, r_n, (n^{1/2}\hat{\Omega}_n^{-1/2}\hat{g}_n, r_n))$$

(19.16)

when $p \geq 2$. Hence, the functional form of Kleibergen’s test statistic differs from that of Moreira’s LR statistic when $p \geq 2$.

Second, for the rank statistics that have been suggested in the literature, viz., those of Cragg and Donald (1996, 1997), Robin and Smith (2000), and Kleibergen and Paap (2006), $rk_n$ is not of the form $r'_n r_n$, when $p \geq 2$.

Third, Moreira’s conditioning statistic is the $k \times p$ matrix $T_n$. Conditioning on this random matrix is equivalent asymptotically to conditioning on the $k \times p$ matrix $n^{1/2}\hat{D}_n$ by Lemma 19.1(f). But, it is not equivalent asymptotically to conditioning on any of the scalar rank statistics considered in the literature when $p \geq 2$.

Fourth, if one weights the conditioning statistic in the way suggested by Kleibergen (2005) and Smith (2007), then the resulting CLR test is not guaranteed to have correct asymptotic size, see Section 5 of AG1. If one weights the conditioning statistic by $\hat{\Omega}_n^{-1}$, as suggested by Newey and Windmeijer (2009) and Guggenberger, Ramalho, and Smith (2012), then the CLR test is guaranteed to have correct asymptotic size under the conditions given in AG1, but the conditioning statistic is not asymptotically equivalent to Moreira’s (2003) conditioning statistic and the difference can be substantial, see Lemma 19.3(b) and (c) for the $p = 1$ case.

20 Simulation Results for Singular and Near-Singular Variance Matrices

Here, we provide some finite-sample simulations of the null rejection probabilities of the nominal 5% SR-AR and SR-CQLR tests when the variance matrix of the moments is singular and near
The model we consider is the following homoskedastic linear IV model: \( y_{1i} = Y_{2i}\beta + U_i \)
and \( Y_{2i} = Z_i'\pi + V_{1i} \), where all quantities are scalars except \( Z_i, \pi \in R^{d_Z} \), \( \theta = (\beta, \pi')' \in R^{\beta+d_Z} \),
\( EU_i = EV_{2i} = 0 \), \( EU_iZ_i = EV_{1i}Z_i = 0^{d_Z} \), and \( E(V_iV_i'|Z_i) = \Sigma_V \) a.s. for \( V_i := (V_{1i}, V_{2i})' \) and some \( 2 \times 2 \) constant matrix \( \Sigma_V \). The corresponding reduced-form equations are \( y_{1i} = Z_i'\pi\beta + V_{1i} \)
and \( Y_{2i} = Z_i'\pi + V_{1i} \), where \( V_{1i} = U_i + V_{2i}\beta \). The moment conditions for \( \theta \) are \( g_i(\theta) = ((y_{1i} - Z_i'\pi\beta)Z_i', (Y_{2i} - Z_i'\pi)Z_i')' \in R^k \), where \( k = 2d_Z \) and \( d_Z \) is the dimension of \( Z_i \). The variance matrix \( \Sigma_V \otimes EZ_iZ_i' \) of \( g_i(\theta_0) = (V_{1i}Z_i', V_{2i}Z_i')' \) is singular whenever the covariance between the reduced-form errors \( V_{1i} \) and \( V_{2i} \) is one (or minus one) or \( EZ_iZ_i' \) is singular. In this model, we are interested in joint inference concerning \( \beta \) and \( \pi \). This is of interest when one wants to see how the magnitude of \( \pi \) affects the range of plausible \( \beta \) values.

We take \( (V_{1i}, V_{2i}) \sim N(0^2, \Sigma_V) \), where \( \Sigma_V \) has unit variances and correlation \( \rho_V, Z_i \sim N(0^2, I_{d_Z}) \),
\( (V_{1i}, V_{2i}) \) and \( Z_i \) are independent, and the observations are i.i.d. across \( i \). The null hypothesis is
\( H_0 : (\beta, \pi) = (\beta_0, \pi_0) \). We consider the values: \( \rho_V = .95, .999, .999, \) and \( 1.0 \); \( n = 250, 500, 1,000, 2,000, 4,000, 8,000, \) and \( 16,000 \); \( \pi_0 = (\pi_{10}, 0, 0, 0)' \), where \( \pi_{10} = \pi_{10n} = C/n^{1/2} \) and \( C = \sqrt{10} \),
which yields a concentration parameter of \( \lambda = \pi'dEZ_iZ_i'\pi = 10 \) for all \( n \geq 1 \); and \( \beta_0 = 0 \). The variance matrix \( \Omega_F \) of the moment functions is singular when \( \rho_V = 1 \) (because \( g_i(\theta_0) = (V_{1i}Z_i', V_{2i}Z_i')' \) a.s.)
and near singular when \( \rho_V \) is close to one. Under \( H_0 \), with probability one, the extra rejection condition in \( (4.7) \) is: reject \( H_0 \) if \( |I_4 - I_4|g_0(\theta_0) \neq 0^4 \), which fails to hold a.s. and, hence, can be ignored in probability calculations made under \( H_0 \). Forty thousand simulation repetitions are employed.

Tables SM-I, SM-II, and SM-III report results for \( k = 8 \) (which corresponds to \( d_Z = 4 \), \( k = 4 \),
and \( k = 12 \), respectively. Table SM-I shows that the SR-AR and SR-CQLR tests have null rejection

---

\[ ^{59} \text{Analogous results for the SR-CQLR}_2 \text{ test are not provided because the moment functions considered are not of the form in } (15.1), \text{ which is necessary to apply the SR-CQLR}_2 \text{ test.} \]

</table>

probabilities that are close to the nominal 5% level for singular and near singular variance matrices
as measured by \( \rho_V \). As expected, the deviations from 5% decrease with \( n \). For all 40,000 simulation
repetitions, all values of \( n \) considered, and \( k = 8 \), we obtain \( \hat{r}_n(\theta_0) = 8 \) when \( \rho_V < 1.0 \)
and \( \hat{r}_n(\theta_0) = 4 \) when \( \rho_V = 1.0 \). The estimator \( \hat{r}_n(\theta_0) \) also makes no errors when \( k = 4 \)
and 12. Tables SM-II and SM-III show that the deviations of the null rejection probabilities from 5% are somewhat
smaller when \( k = 4 \) and \( n \leq 1000 \) than when \( k = 8 \), and somewhat larger when \( k = 12 \) and \( n \leq 500 \).
The results for \( k = 8 \) and \( C = 0, 2, \sqrt{30} \), and 10 are similar. For brevity, these results are not
reported.

We conclude that the method introduced in Section 4 to make the SR-AR and SR-CQLR tests
robust to singularity works very well in the model that is considered in the simulations.
21 Simulation Results for Kleibergen’s MVW-CLR Test

This section presents finite-sample simulation results that show that Kleibergen’s (2005) CLR test with moment-variance weighting (MVW-CLR) has low power in some scenarios in the homoskedastic linear IV model with normal errors, relative to the power of the SR-CQLR and SR-CQLR_P tests, Kleibergen’s CLR test with Jacobian-variance weighting (JVW-CLR), and the CLR test of Moreira (2003) (Mor-CLR).\footnote{The MVW-CLR and JVW-CLR tests denote Kleibergen’s (2005) CLR test with the rank statistic given by the Robin and Smith (2000) statistics \( r_k = \lambda \min(n\hat{D}_n\hat{\Omega}_n^{-1/2}\hat{D}_n) \) and \( r_k = \lambda \min(n\hat{D}_n\hat{V}_e\hat{S}_n^{-1}\hat{D}_n) \), respectively, where \( \hat{\Omega}_n \) and \( \hat{D}_n \) are defined in (4.1) and (5.2) with \( \theta = \theta_0 \) and \( \hat{V}_e\hat{S}_n \) is an estimator of the asymptotic variance of \( \hat{D}_n \) (after suitable normalization) and is defined in (19.12). Note that the second formula for \( r_k \) is appropriate only for the case \( p = 1 \), which is the case considered here. The estimators \( \hat{D}_n \) and \( \hat{V}_e\hat{S}_n \) are estimators of the asymptotic variances of the sample moments and Jacobian, respectively, which leads to the MVW and JVW terminology.}

As noted at the beginning of Section 19.5, Lemma 19.3 and Comment (iv) following it show that the scale (denoted by \( \text{scale} \) below) of the moment-variance weighting conditioning statistic can be far from the optimal value of one.\footnote{The constant \( \text{scale} \) is the constant \( (L\sqrt{b_0}\Sigma V b_0)^{-1} \) in Lemma 19.3(b) and (c).}

We provide results for one scenario where \( \text{scale} \) is too large and one scenario where it is too small. These scenarios are chosen based on the formula given in Lemma 19.3.

The model is the homoskedastic normal linear IV model introduced in Section 19.1 with unknown error variance matrix \( \Sigma_V \) and \( p = 1 \). The IV’s are fixed—they are generated once from a \( N(0^k, I_k) \) distribution. The sample size \( n \) equals 1,000. The hypotheses are \( H_0 : \theta = 0 \) and \( H_1 : \theta \neq 0 \). The tests have nominal size .05. The power results are based on 40,000 simulation repetitions and 1,000 critical value repetitions and are size-corrected (by adding non-negative constants to the critical values of those tests that over-reject under the null). The reduced-form error variances and correlation are denoted by \( \Sigma_{V11}, \Sigma_{V22}, \) and \( \rho \), respectively, and \( \lambda := \pi'Z'Z\pi \). The number of IV’s is \( k \). The MVW-CLR and JVW-CLR tests employ the Robin and Smith (2000) rank statistic. Results are reported for the tests discussed above, as well as Kleibergen’s LM test and the AR test.

Design 1 takes \( \Sigma_{V11} = 1.0, \Sigma_{V22} = 4.0, \rho = 0.5, \pi = 0.044, \lambda = 2.009, \) and \( k = 5 \). These parameter values yield \( \text{scale} = 30.0 \), which results in the MVW-CLR test behaving like Kleibergen’s LM test even though the LM test has low power in this scenario. Design 2 takes \( \Sigma_{V11} = 3.0, \Sigma_{V22} = 0.1, \rho = 0.95, \pi = 0.073, \lambda = 4.995, \) and \( k = 10 \). These parameter values yield \( \text{scale} = 0.0033 \), which results in the MVW-CLR test behaving like the AR test even though the AR test has low power in this scenario.

The power functions of the tests are reported in Figure SM-2 (with \( \theta\lambda^{1/2} \) on the horizontal axes with \( \lambda^{1/2} \) fixed). Figure SM-2(a) shows that, for Design 1, the MVW-CLR and LM tests have very similar power functions and both are substantially below the power functions of the SR-CQLR,
SR-CQLR, JVW-CLR, and Mor-CLR tests, which have essentially equal and optimal power. The AR test has high power, like that of the SR-CQLR, SR-CQLR, JVW-CLR, and Mor-CLR tests, for positive $\theta$, and low power, like that of the MVW-CLR and LM tests, for negative $\theta$.

Figure SM-2(b) shows that, for Design 2, the MVW-CLR and AR tests have similar power functions and both are substantially below the power functions of the SR-CQLR, SR-CQLR, JVW-CLR, Mor-CLR, and LM tests, which have essentially equal and optimal power.

22 Eigenvalue-Adjustment Procedure

Eigenvalue adjustments are made to two sample matrices that appear in the SR-CQLR and SR-CQLR test statistics. These adjustments guarantee that the adjusted sample matrices have minimum eigenvalues that are not too close to zero even if the corresponding population matrices are singular or near singular. These adjustments improve the asymptotic and finite-sample performance of the tests by improving their robustness to singularities or near singularities.

The eigenvalue-adjustment procedure can be applied to any non-zero psd matrix $H \in R^{d_H \times d_H}$ for some positive integer $d_H$. Let $\varepsilon$ be a positive constant. Let $A_H \Lambda_H A_H'$ be a spectral decomposition of $H$, where $\Lambda_H = Diag\{\lambda_{H1}, ..., \lambda_{Hd_H}\} \in R^{d_H \times d_H}$ is the diagonal matrix of eigenvalues of $H$ with nonnegative nonincreasing diagonal elements and $A_H$ is a corresponding orthogonal matrix of eigenvectors of $H$. The eigenvalue-adjusted matrix $H^\varepsilon \in R^{d_H \times d_H}$ is

$$H^\varepsilon := A_H \Lambda_H^\varepsilon A_H', \text{ where } \Lambda_H^\varepsilon := Diag\{\max\{\lambda_{H1}, \lambda_{\max}(H)\varepsilon\}, ..., \max\{\lambda_{Hd_H}, \lambda_{\max}(H)\varepsilon\}\}. \quad (22.1)$$

We have $\lambda_{\max}(H) = \lambda_{H1}$, and $\lambda_{\max}(H) > 0$ provided the psd matrix $H$ is non-zero.

The following lemma provides some useful properties of this eigenvalue adjustment procedure.

Lemma 22.1 Let $d_H$ be a positive integer, let $\varepsilon$ be a positive constant, and let $H \in R^{d_H \times d_H}$ be a non-zero positive semi-definite non-random matrix. Then,

(a) (uniqueness) $H^\varepsilon$, defined in (22.1), is uniquely defined. (That is, every choice of spectral decomposition of $H$ yields the same matrix $H^\varepsilon$),

(b) (eigenvalue lower bound) $\lambda_{\min}(H^\varepsilon) \geq \lambda_{\max}(H)\varepsilon$,

(c) (condition number upper bound) $\lambda_{\max}(H^\varepsilon)/\lambda_{\min}(H^\varepsilon) \leq \max\{1/\varepsilon, 1\}$,

(d) (scale equivariance) For all $c > 0$, $(cH)^\varepsilon = cH^\varepsilon$, and

(e) (continuity) $H^\varepsilon_n \to H^\varepsilon$ for any sequence of psd matrices $\{H_n \in R^{d_H \times d_H} : n \geq 1\}$ that satisfies $H_n \to H$. 

57
Proof of Lemma 22.1. For notational simplicity, we drop the $H$ subscript on $A_H$, $\Lambda_H$, and $\Lambda_H^\varepsilon$. We prove part (a) first. The eigenvectors of $H^\varepsilon (= A\Lambda^\varepsilon A')$ defined in (5.6) are unique up to the choice of vectors that span the eigenspace that corresponds to any eigenvalue. Suppose the $j$, $j + d$ eigenvalues of $H$ are equal for some $d \geq 0$ and $1 \leq j < d_H$. We can write $A = (A_1, A_2, A_3)$, where $A_1 \in R^{d_H \times (j - 1)}$, $A_2 \in R^{d_H \times (d + 1)}$, and $A_3 \in R^{d_H \times (d_H - j - d)}$. In addition, $H$ can be written as $H = A_* \Lambda A'_*$, where $A_* = (A_1, A_2, A_3)$, the column space of $A_2$ equals that of $A_2$, and $A_*$ is an orthogonal matrix. As above, $H^\varepsilon = A \Lambda^\varepsilon A'$. To establish part (a), if suffices to show that $H^\varepsilon = A_* \Lambda^\varepsilon A'_*$, or equivalently, $A \Lambda A' \xi = A_* \Lambda^\varepsilon A'_* \xi$ for any $\xi \in R^{d_H}$.

For any $\xi \in R^{d_H}$, we can write $\xi = \xi_1 + \xi_2$, where $\xi_1$ belongs to the column space of $A_2$ (and $A_2$) and $\xi_2$ is orthogonal to this column space. We have

$$A \Lambda^\varepsilon A' \xi = A \Lambda^\varepsilon (A_1, A_2, A_3)'(\xi_1 + \xi_2)$$

$$= A \Lambda^\varepsilon (0^{j-1}, (A_2^\varepsilon \xi_2), 0^{d_H - j - d})' + A \Lambda^\varepsilon ((A_1^\varepsilon \xi_2)', 0^{d_H - 1}, (A_3^\varepsilon \xi_2))'$$

$$= A \Lambda_j^\varepsilon (0^{j-1}, (A_2^\varepsilon \xi_2), 0^{d_H - j - d})' + (A_1, A_2, A_3) \Lambda^\varepsilon ((A_1^\varepsilon \xi_2)', 0^{d_H - 1}, (A_3^\varepsilon \xi_2))'$$

$$= A_2 A_2^\varepsilon \xi_2 \lambda_j^\varepsilon + (A_1, A_3) \Lambda^\varepsilon ((A_1^\varepsilon \xi_2)', (A_3^\varepsilon \xi_2))'$$

$$= A_2 A_2^\varepsilon \xi_2 \lambda_j^\varepsilon + (A_1, A_3) \Lambda^\varepsilon ((A_1^\varepsilon \xi_2)', (A_3^\varepsilon \xi_2))'$$

$$= A_* \Lambda^\varepsilon A'_* \xi,$$

(22.2)

where $\Lambda^\varepsilon \in R^{(d_H - d - 1) \times (d_H - d - 1)}$ is the diagonal matrix equal to $\Lambda^\varepsilon$ with its $j$, $j + d$ rows and columns deleted, $\lambda_j^\varepsilon = \max \{\lambda_j, \lambda_{\max}(H)^\varepsilon\}$, $\lambda_j$ is the $j$th eigenvalue of $\Lambda$, and the second equality uses $A'_1 \xi_1 = 0^{j-1}$, $A'_3 \xi_2 = 0^{d_H - j - d}$, and $A_2^\varepsilon \xi_2 = 0^{d_H - 1}$, the third equality holds because $\lambda_j = \ldots = \lambda_{j + d}$ implies that $\lambda_j^{\varepsilon} = \ldots = \lambda_{j + d}^{\varepsilon}$, the fourth equality holds using the definition of $\Lambda^\varepsilon$, the fifth equality holds because $A_2 A_2^\varepsilon = A_2 A_2^\varepsilon$ (since both equal the projection matrix onto the column space of
$A_2$ (and $A_{2s}$)), and the last equality holds by reversing the steps in the previous equalities with
$A_s = (A_1, A_{2s}, A_3)$ in place of $A = (A_1, A_2, A_3)$. Because (22.2) holds for any matrix $A_{2s}$ defined
as above and any feasible $j$ and $d$, part (a) holds.

To prove parts (b) and (c), we note that the eigenvalues of $H^\varepsilon$ are $\{\max\{\lambda_{H, j}, \lambda_{\max}(H)\varepsilon\} : j = 1, \ldots, d_H\}$ because $H^\varepsilon = A\Lambda^\varepsilon A'$ and $A$ is an orthogonal matrix. In consequence, $\lambda_{\min}(H^\varepsilon) \geq \lambda_{\max}(H)\varepsilon$, which establishes part (b). If $\lambda_{\min}(H) > \lambda_{\max}(H)\varepsilon$, then $H^\varepsilon = H$, $\lambda_{\max}(H^\varepsilon)/\lambda_{\min}(H^\varepsilon) = \lambda_{\max}(H)/\lambda_{\min}(H) < 1/\varepsilon$, and the result of part (c) holds. Alternatively, if $\lambda_{\min}(H) \leq \lambda_{\max}(H)\varepsilon$, then $\lambda_{\min}(H^\varepsilon) = \lambda_{\max}(H)\varepsilon$. In addition, we have $\lambda_{\max}(H^\varepsilon) = \max\{\lambda_{H1}, (\lambda_{\max}(H)\varepsilon) = \lambda_{\max}(H) \times \max\{1, \varepsilon\}$ using $\lambda_{H1} = \lambda_{\max}(H)$. Combining these two results gives $\lambda_{\max}(H^\varepsilon)/\lambda_{\min}(H^\varepsilon) = \lambda_{\max}(H) \max\{1, \varepsilon\}/(\lambda_{\max}(H)\varepsilon) = \max\{1/\varepsilon, 1\}$, where the second equality uses the assumption that $H$ is non-zero, which implies that $\lambda_{\max}(H) > 0$. This gives the result of part (c).

We now prove part (d) and for clarity make the $H$ subscripts on $A_H$ and $\Lambda_H$ explicit in this
paragraph. We have $\Lambda_{cH} = c\Lambda_H$ and we can take $A_{cH} = A_H$ by the definition of eigenvalues and
eigenvectors. This implies that $\Lambda^\varepsilon_{cH} = c\Lambda^\varepsilon_H$ (using the definition of $\Lambda^\varepsilon_H$ in (5.6)) and $(cH)^\varepsilon = A_{cH}\Lambda^\varepsilon_{cH}A'_{cH} = cA_HI\Lambda^\varepsilon_H cA' = cH^\varepsilon$, which establishes part (d).

Now we prove part (e). Let $A_n\Lambda_n A'_n$ be a spectral decomposition of $H_n$ for $n \geq 1$. Let $H^\varepsilon_n = A_n\Lambda^\varepsilon_n A'_n$ for $n \geq 1$, where $\Lambda^\varepsilon_n$ is the diagonal matrix with $j$th diagonal element given by $\lambda^\varepsilon_{nj} = \max\{\lambda_{nj}, \lambda_{\max}(H_n)\varepsilon\}$ and $\lambda_{nj}$ is the $j$th largest eigenvalue of $H_n$. (By part (a) of the Lemma, $H^\varepsilon_n$ is invariant to the choice of eigenvector matrix $A_n$ used in its definition.)

Given any subsequence $\{n_k\}$ of $\{n\}$, let $\{n_m\}$ be a subsubsequence such that $A_{n_m} \to A$ for
some orthogonal matrix $A$ that may depend on the subsubsequence $\{n_m\}$. (Such a subsubsequence exists because the set of orthogonal $d_H \times d_H$ matrices is compact.) By assumption, $H_n \to H$. This
implies that $\Lambda_n \to \Lambda$, where $\Lambda$ is the diagonal matrix of eigenvalues of $H$ in nonincreasing order
(by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38)). In turn, this gives $\Lambda^\varepsilon_n \to \Lambda^\varepsilon$, where $\Lambda^\varepsilon$ is the diagonal matrix with $j$th diagonal element given by $\lambda^\varepsilon_j = \max\{\lambda_j, \lambda_{\max}(H)\varepsilon\}$ and $\lambda_j$ is the $j$th largest eigenvalue of $H$, because $\lambda_{\max}(\cdot)$ is a continuous function (by Elsner’s
Theorem again). The previous results imply that $H_{nm} = A_{nm}\Lambda_{nm} A'_{nm} \to A\Lambda A'$, $H = A\Lambda A'$,
$H^\varepsilon_{nm} = A_{nm}\Lambda^\varepsilon_{nm} A'_{nm} \to A\Lambda^\varepsilon A'$, and $A\Lambda^\varepsilon A' = H^\varepsilon$. Because every subsequence $\{n_k\}$ of $\{n\}$ has a
subsubsequence $\{n_m\}$ for which $H^\varepsilon_{nm} \to H^\varepsilon$, we obtain $H^\varepsilon_n \to H^\varepsilon$, which completes the proof of
part (e). □

59
23 Singularity-Robust LM Test

SR-LM versions of Kleibergen’s LM test and CS can be defined analogously to the SR-AR and SR-CQLR tests and CS’s. However, these procedures are only partially singularity robust, see the discussion below. In addition, LM tests have low power in some circumstances under weak identification.

The SR-LM test statistic is

$$\text{SR-LM}_n(\theta) := n\hat{g}_An(\theta)\hat{P}_{\omega}\hat{D}_An(\theta)\hat{g}_An(\theta),$$

where $P_M$ denotes the projection matrix onto the column space of the matrix $M$. For testing $H_0 : \theta = \theta_0$, the SR-LM test rejects the null hypothesis if

$$\text{SR-LM}_n(\theta_0) > \chi^2_{\min\{\hat{r}_n(\theta_0), p\}, 1 - \alpha},$$

where $\chi^2_{\min\{\hat{r}_n(\theta_0), p\}, 1 - \alpha}$ denotes the $1 - \alpha$ quantile of a chi-squared distribution with $\min\{\hat{r}_n(\theta_0), p\}$ degrees of freedom. This test can be shown to have correct asymptotic size and to be asymptotically similar for the parameter space $\mathcal{F}^{SR}_{LM}$, which is a generalization of the parameter space $\mathcal{F}_0$ in AG1 and has a similar (rather complicated) form to $\mathcal{F}_0$. It is defined as follows: for some $\delta_1 > 0$,

$$\mathcal{F}^{SR}_{LM} := \bigcup_{j=0}^{\min\{r_F, p\}} \mathcal{F}^{SR}_{LM_j},$$

where

$$\mathcal{F}^{SR}_{LM_j} := \{F \in \mathcal{F}^{SR} : \tau^*_{jF} \geq \delta_1 \text{ and } \lambda_{p-j} \left( \Psi_F^{C^*_F{k-j}G^*_iB^*_i, p-j, \xi} \right) \geq \delta_1 \forall \xi \in R^{p-j} \text{ with } ||\xi|| = 1, \right.$$

$$G^*_i := \Pi^{-1/2}_{1F}A^*_Fi \in R^{r_F \times p}, r_F := rk(\Omega_F), g^*_i := \Pi^{-1/2}_{1F}A^*_Fi \in R^{r_F},$$

$$\Psi_{a_i} := E_Fa_i^a_i - E_Fa_ig^*_i(E_Fg^*_iE_F)^{-1}E_Fg^*_ia_i$$

for any random vector $a_i$,

$$\tau^*_{jF}$$ is the $j$th largest singular value of $E_FG^*_i$ for $j = 1, ..., \min\{r_F, p\}$, $\tau^*_{0F} := \delta_1$, $B^*_F$ is a $p \times p$ orthogonal matrix of eigenvalues of $(E_FG^*_i)'(E_FG^*_i)$ ordered so that the corresponding eigenvalues $(\kappa^*_1, ..., \kappa^*_p)$ are nonincreasing, $C^*_F$ is an $r_F \times r_F$ orthogonal matrix of eigenvalues of $(E_FG^*_i)'(E_FG^*_i)'$ ordered so that the corresponding eigenvalues $(\kappa^*_1, ..., \kappa^*_r_F)$ are nonincreasing, $B^*_j := \begin{pmatrix} B^*_{F,j} & B^*_{F,p-j} \end{pmatrix}$ for $B^*_{F,j} \in R^{r_F \times j}$ and $B^*_{F,k-j} \in R^{r_F \times (p-j)}$, and $C^*_F := \begin{pmatrix} C^*_{F,j} & C^*_{F,k-j} \end{pmatrix}$ for $C^*_{F,j} \in R^{r_F \times j}$ and $C^*_{F,k-j} \in R^{r_F \times (r_F-j)}$.

See Section 3 of AG1 for a discussion of the form of this condition is invariant to the choice of $B^*_F$ and $C^*_F$.

---

\(^{62}\) The first $\min\{r_F, p\}$ eigenvalues of $(E_FG^*_i)'(E_FG^*_i)$ and $(E_FG^*_i)'(E_FG^*_i)'$ are the same. If $r_F > p$, the remaining $r_F - p$ eigenvalues of $(E_FG^*_i)'(E_FG^*_i)'$ are all zeros. If $r_F < p$, the remaining $p - r_F$ eigenvalues of $(E_FG^*_i)'(E_FG^*_i)'$ are all zeros.

\(^{63}\) The matrices $B^*_F$ and $C^*_F$ are not necessarily uniquely defined. But, this is not of consequence because the $\lambda_{p-j}(\cdot)$ condition is invariant to the choice of $B^*_F$ and $C^*_F$. 

60
parameter space and the quantities upon which it depends. Note that $\Psi^{a_i}_F$ is the expected outer-product matrix of the vector of residuals, $a_i - E_F a_i g_i^s (E_F g_i^s g_i^*)^{-1} g_i^*$, from the $L^2(F)$ projections of $a_i$ onto the space spanned by the components of $g_i^*$, see AG1 for further discussion.

The conditions in $\mathcal{F}_{LM}^{SR}$ (beyond those in $\mathcal{F}^{SR}$) are used to guarantee that the conditioning matrix $\tilde{D}_{An} \in \mathbb{R}^{n \times p}$ has full rank $\min\{\hat{r}_n, p\}$ asymptotically with probability one (after pre- and post-multiplication by suitable matrices). AG1 shows that these conditions are not redundant. Given the need for these conditions, the SR-LM test is not fully singularity robust. The asymptotic size and similarity result for the SR-LM test stated above can be proved using Theorem 4.1 of AG1 combined with the argument given in Section 17 below. For brevity, we do not provide the details. Extensions of the asymptotic size and similarity results to SR-LM CS’s are analogous to those for the SR-AR and SR-CQLR CS’s.

A theoretical advantage of the SR-AR and SR-CQLR tests and CS’s considered in this paper, relative to tests and CS’s that make use of the LM statistic, is that they avoid the complicated conditions that appear in $\mathcal{F}_{LM}^{SR}$.

## 24 Proofs of Lemmas 16.2, 5.1, and 15.1

**Lemma 16.2** of AG2. Let $D$ be a $k \times p$ matrix with the singular value decomposition $D = C \Upsilon Y'$, where $C$ is a $k \times k$ orthogonal matrix of eigenvectors of $D D'$, $B$ is a $p \times p$ orthogonal matrix of eigenvectors of $D' D$, and $\Upsilon$ is the $k \times p$ matrix with the $\min\{k, p\}$ singular values $\{\tau_j : j \leq \min\{k, p\}\}$ of $D$ as its first $\min\{k, p\}$ diagonal elements and zeros elsewhere, where $\tau_j$ is nonincreasing in $j$. Then, $c_{k,p}(D, 1 - \alpha) = c_{k,p}(\Upsilon, 1 - \alpha)$.

**Proof of Lemma 16.2** Define

\[
B^+ := \begin{bmatrix} B & 0^p \\ 0^{p'} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1) \times (p+1)}.
\] (24.1)

The matrix $B^+$ is orthogonal because $B$ is, where $B$ is as in the statement of the lemma. The
eigenvalues of \((D, Z)'(D, Z)\) are solutions \(\{\kappa_j : j \leq p + 1\}\) to

\[
|\(D, Z)'(D, Z) - \kappa I_{p+1}| = 0 \text{ or } \\
|B'^*(D, Z)'(D, Z)B^+ - \kappa I_{p+1}| = 0 \text{ or } \\
|\(DB, Z)'(DB, Z) - \kappa I_{p+1}| = 0, \text{ or } \\
|\(CY, Z)'CC'(CY, Z) - \kappa I_{p+1}| = 0, \text{ or,}
\]

\[
|\(\Upsilon, Z^*')'(\Upsilon, Z^*) - \kappa I_{p+1}| = 0, \text{ where } Z^* := C'Z \sim N(0^k, I_k), \quad (24.2)
\]

the equivalence of the first and second lines holds because \(|A_1A_2| = |A_1| \cdot |A_2|, |B^+| = 1, \text{ and } B'^*B^+ = I_{p+1}\), the equivalence of the second and third lines holds by matrix algebra, the equivalence of the third and fourth lines holds because \(DB = CYB'B = CY\) and \(CC' = I_k\), and the equivalence of the last two lines holds by \(CC' = I_k\) and the definition of \(Z^*\). Equation (24.2) implies that \(\lambda_{\text{min}}((D, Z)'(D, Z))\) equals \(\lambda_{\text{min}}((\Upsilon, Z^*)'(\Upsilon, Z^*))\). In addition, \(Z'Z = Z'^*Z^*\). Hence

\[
\text{CLR}_{k,p}(D) = Z'Z - \lambda_{\text{min}}((D, Z)'(D, Z)) = Z'^*Z^* - \lambda_{\text{min}}((\Upsilon, Z^*)'(\Upsilon, Z^*)). \quad (24.3)
\]

Since \(Z\) and \(Z^*\) have the same distribution, \(\text{CLR}_{k,p}(D) = Z'^*Z^* - \lambda_{\text{min}}((\Upsilon, Z^*)'(\Upsilon, Z^*))\) and \(\text{CLR}_{k,p}(\Upsilon) = Z'Z - \lambda_{\text{min}}((\Upsilon, Z)'(\Upsilon, Z))\) have the same distribution and the same \(1 - \alpha\) quantile. That is, \(c_{k,p}(D, 1 - a) = c_{k,p}(\Upsilon, 1 - \alpha)\). \(\square\)

**Lemma 5.1 of AG2.** The statistics \(\text{QLR}_n, c_{k,p}(n^{1/2}\hat{D}_n^*, 1 - \alpha), \hat{D}_n^*\), \(\hat{\Sigma}_n\), and \(\hat{\Upsilon}_n\) are invariant to the transformation \((g_i, G_i) \sim (Mg_i, MG_i) \forall i \leq n\) for any \(k \times k\) nonsingular matrix \(M\). This transformation induces the following transformations: \(\hat{g}_n \sim M\tilde{g}_n, \hat{G}_n \sim M\tilde{G}_n, \hat{\Omega}_n \sim M\tilde{\Omega}_nM', \hat{\Gamma}_n \sim M\tilde{\Gamma}_nM' \forall j \leq p, \hat{D}_n \sim M\tilde{D}_n, \hat{V}_n \sim (I_{p+1} \otimes M)\tilde{V}_n (I_{p+1} \otimes M'), \text{ and } \hat{R}_n \sim (I_{p+1} \otimes M)\tilde{R}_n (I_{p+1} \otimes M').\)

**Proof of Lemma 5.1.** We refer to the results of the Lemma for \(g_i, G_i, ..., \hat{R}_n\) as equivariance results. The equivariance results are immediate for \(g_i, G_i, \hat{g}_n, \hat{G}_n, \hat{\Omega}_n, \text{ and } \hat{\Gamma}_n\). For \(\hat{D}_n = (\hat{D}_1, ..., \hat{D}_p)\), we have

\[
\hat{D}_{jn} := \hat{G}_{jn} - \hat{\Gamma}_{jn}\hat{\Omega}^{-1}_{jn}\hat{g}_n \sim M\tilde{G}_{jn} - M\tilde{\Gamma}_{jn}M'(M\tilde{\Omega}_nM')^{-1}M\tilde{g}_n = M\tilde{D}_{jn} \quad (24.4)
\]

for \(j = 1, ..., p\). We have \(f_i := (g_i', \text{vec}(G_i)')' \sim ((Mg_i)'', \text{vec}(MG_i)')' = (I_{p+1} \otimes M) f_i\). Using this, we obtain \(\hat{V}_n = n^{-1}\sum_{i=1}^n (f_i - \hat{f}_n)(f_i - \hat{f}_n)' \sim (I_{p+1} \otimes M)\hat{V}_n (I_{p+1} \otimes M')\). Next, we have

\[\text{CLR}_{k,p}(D)\text{ is written in terms of } (D, Z)\text{ in (24.3), whereas it is written in terms of } (Z, D)\text{ in (5.8). Both expressions give the same value.}\]
\(\hat{R}_n := (B' \otimes I_k) \hat{V}_n (B \otimes I_k) \sim (B' \otimes M) \hat{V}_n (B \otimes M') = (I_{p+1} \otimes M) \hat{R}_n (I_{p+1} \otimes M')\) using the equivariance result for \(\hat{V}_n\). We have \(\Sigma_{j_\ell} := tr(\hat{R}'_{j_\ell n} \hat{\Omega}_n^{-1})/k \sim tr((M \hat{R}'_{j_\ell n} M')(M \hat{\Omega}_n M')^{-1})/k = tr(M \hat{R}'_{j_\ell n} M' M^{-1} \hat{\Omega}_n^{-1} M^{-1})/k = \hat{\Sigma}_{j_\ell n}\) for \(j, \ell = 1, \ldots, p + 1\) using the equivariance result for \(\hat{R}_n\). We have \(\hat{L}_n := (\theta, I_{p}) (\hat{\Sigma}_n^z)^{-1} (\theta, I_{p})' \sim \hat{L}_n\) using the invariance result for \(\hat{\Sigma}_n\). We have \(\hat{D}' \hat{D}_n^* := \hat{L}'_{1/2} \hat{D}_n' \hat{\Omega}_n^{-1} \hat{D}_n \hat{L}_n^{-1/2} \sim \hat{L}'_{1/2} \hat{D}_n' M'(M \hat{\Omega}_n M')^{-1} M \hat{D}_n \hat{L}_n^{-1/2} = \hat{D}' \hat{D}_n^*\). This implies that \(c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha) \sim c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha)\) because \(c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha)\) only depends on \(\hat{D}_n^*\) through \(\hat{D}' \hat{D}_n^*\) by the Comment to Lemma \ref{16.2}

We have \(AR_n := n \hat{g}_n \hat{\Omega}_n^{-1/2} \hat{g}_n \sim n \hat{g}_n M'(M \hat{\Omega}_n M')^{-1} M \hat{g}_n = AR_n\). We have

\[
QLR_n := AR_n - \min \left( \frac{n \hat{g}_n \hat{D}_n \hat{L}_n^{-1/2}}{\hat{\Omega}_n} \right) \sim AR_n - \min \left( \frac{n M \hat{g}_n M \hat{D}_n \hat{L}_n^{-1/2}}{(M \hat{\Omega}_n M')^{-1}} \right)
\]

using the invariance of \(AR_n\) and \(\hat{L}_n\) and the equivariance of the other statistics that appear. \(\square\)

**Lemma 15.1.** The statistics \(QLR_{Pn}, c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha), \hat{D}' \hat{D}_n^*, AR_n, \hat{\alpha}_n, \hat{\Sigma}_n,\) and \(\hat{L}_n\) are invariant to the transformation \((Z_i, u_i^*) \sim (MZ_i, u_i^*)\) \(\forall i \leq n\) for any \(k \times k\) nonsingular matrix \(M\).

This transformation induces the following transformations: \(g_i \sim Mg_i, \forall i \leq n, G_i \sim MG_i, \forall i \leq n, \hat{g}_n \sim M \hat{g}_n, \hat{G}_n \sim M \hat{G}_n, \hat{\Sigma}_n \sim M \hat{\Sigma}_n M', \hat{\alpha}_n \sim M \hat{\alpha}_n M', \hat{L}_n \sim \hat{L}_n M', \forall j \leq p, \hat{D}_n \sim M \hat{D}_n, \hat{\Omega}_n \sim M \hat{\Omega}_n M', \hat{\Sigma}_n \sim M^{-1} \hat{\Sigma}_n, \hat{\alpha}_n \sim (I_{p+1} \otimes M) \hat{\alpha}_n (I_{p+1} \otimes M'), \) and \(\hat{L}_n \sim (I_{p+1} \otimes M) \hat{L}_n (I_{p+1} \otimes M')\).

**Proof of Lemma 15.1.** We refer to the results of the Lemma for \(g_i, G_i, \ldots, \hat{R}_n\) as equivariance results. The equivariance results are immediate for \(g_i, G_i, \hat{g}_n, \hat{G}_n, \hat{\Sigma}_n, \hat{\alpha}_n, \hat{L}_n\), and \(Z_{n \times k}\).

For \(\hat{D}_n = (\hat{D}_{1n}, \ldots, \hat{D}_{pn})\), we have \(\hat{D}_{jn} \sim M \hat{D}_{jn}\) for \(j = 1, \ldots, p\) by (24.4) above. In addition, we have \(\hat{\Sigma}_n := (Z_{n \times k} Z_{n \times k})^{-1} Z_{n \times k} U^* \sim (MZ_{n \times k} Z_{n \times k})^{-1} M Z_{n \times k} U^* = M^{-1} \hat{\Sigma}_n\). We have \(\hat{\alpha}_n := \hat{\alpha}_n Z_i \sim (M^{-1} \hat{\Sigma}_n) U M Z_i = \hat{\alpha}_n\). We have \(\hat{\alpha}_n := n^{-1} \sum_{i=1}^n ((u_i^* - \hat{\alpha}_n)(u_i^* - \hat{\alpha}_n)' \otimes Z_i Z_i'); \sim n^{-1} \sum_{i=1}^n ((u_i^* - \hat{\alpha}_n)(u_i^* - \hat{\alpha}_n)' \otimes M Z_i Z_i') = (I_{p+1} \otimes M) \hat{\alpha}_n (I_{p+1} \otimes M')\) using the invariance of \(\hat{\alpha}_n\). We have \(\hat{R}_n := (B' \otimes I_k) \hat{V}_n (B \otimes I_k) \sim (B' \otimes M) \hat{V}_n (B \otimes M') = (I_{p+1} \otimes M) \hat{R}_n (I_{p+1} \otimes M')\) using the equivariance result for \(\hat{V}_n\).

We have \(\Sigma_{j_\ell} := tr(\hat{R}'_{j_\ell n} \hat{\Omega}_n^{-1})/k \sim tr((M \hat{R}'_{j_\ell n} M')(M \hat{\Omega}_n M')^{-1})/k = tr(M \hat{R}'_{j_\ell n} M' M^{-1} \hat{\Omega}_n^{-1} M^{-1})/k = \Sigma_{j_\ell n}\) for \(j, \ell = 1, \ldots, p + 1\) using the equivariance result for \(\hat{R}_n\). We have \(\hat{L}_n := (\theta, I_{p}) (\hat{\Sigma}_n^z)^{-1} (\theta, I_{p})' \sim \hat{L}_n\) using the invariance result for \(\hat{\Sigma}_n\). We have \(\hat{D}' \hat{D}_n^* := \hat{L}'_{1/2} \hat{D}_n' \hat{\Omega}_n^{-1} \hat{D}_n \hat{L}_n^{-1/2} \sim \hat{L}'_{1/2} \hat{D}_n' M'(M \hat{\Omega}_n M')^{-1} M \hat{D}_n \hat{L}_n^{-1/2} = \hat{D}' \hat{D}_n^*\). This implies that \(c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha) \sim c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha)\) because \(c_{k,p}(n^{1/2} \hat{D}_n^*, 1 - \alpha)\) only depends on \(\hat{D}_n^*\) through \(\hat{D}' \hat{D}_n^*\) by the Comment to Lemma \ref{16.2}

We have \(AR_n\) and \(QLR_{Pn}\) are invariant by the argument in the paragraph above that contains
25 Proofs of Lemma [16.4] and Proposition [16.5]

Lemma [16.4] Suppose Assumption WU holds for some non-empty parameter space \( \Lambda_* \subset \Lambda_{WU} \). Under all sequences \( \{\lambda_{n,h} : n \geq 1\} \) with \( \lambda_{n,h} \in \Lambda_* \),

\[
n^{1/2}(\bar{g}_n, \bar{D}_n - E_n G_i, W_n, D_n U_n T_n) \rightarrow_d (\bar{g}_h, \bar{D}_h, \bar{\Sigma}_h),
\]

where (a) \((\bar{g}_h, \bar{D}_h)\) are defined in (16.21), (b) \(\bar{\Sigma}_h\) is the nonrandom function of \(h\) and \(\bar{D}_h\) defined in (16.24), (c) \((\bar{D}_h, \bar{\Sigma}_h)\) and \(\bar{g}_h\) are independent, and (d) under all subsequences \(\{w_n\}\) and all sequences \(\{\lambda_{w_n,h} : n \geq 1\} \) with \(\lambda_{w_n,h} \in \Lambda_*\), the convergence result above and results of parts (a)-(c) hold with \(n\) replaced with \(w_n\).

Here and below, we use the following simplified notation:

\[
D_n := E_n G_i, \quad B_n := B_n, \quad C_n := C_n, \quad B_n = (B_{n,q}, B_{n,p-q}), \quad C_n = (C_{n,q}, C_{n,k-q}),
\]

\[
W_n := W_n, \quad W_2 := W_2, \quad U_n := U_n, \quad \text{and } U_2 := U_2,
\]

where \(q = q_h\) is defined in (16.22). \(B_{n,q} \in R^{p \times q}, \quad B_{n,p-q} \in R^{(p-q) \times (p-q)}, \quad C_{n,q} \in R^{k \times q}, \quad \text{and } C_{n,k-q} \in R^{k \times (k-q)}\). Let

\[
Y_{n,q} := \text{Diag} \{\tau_{1F_n}, \ldots, \tau_{qF_n}\} \in R^{q \times q},
\]

\[
Y_{n,p-q} := \text{Diag} \{\tau_{(q+1)F_n}, \ldots, \tau_{pF_n}\} \in R^{(p-q) \times (p-q)} \text{ if } k \geq p,
\]

\[
Y_{n,k-q} := \text{Diag} \{\tau_{(q+1)F_n}, \ldots, \tau_{kF_n}\} \in R^{(k-q) \times (k-q)} \text{ if } k < p,
\]

\[
Y_n := \begin{bmatrix}
Y_{n,q} & 0^{q \times (p-q)} \\
0^{(p-q) \times q} & Y_{n,p-q} \\
0^{(k-p) \times q} & 0^{(k-p) \times (p-q)} \\
0^{(k-q) \times q} & 0^{(k-q) \times (p-q)} \\
\end{bmatrix} \in R^{k \times p} \text{ if } k \geq p, \quad \text{and}
\]

\[
Y_n := \begin{bmatrix}
Y_{n,q} & 0^{q \times (k-q)} & 0^{q \times (p-k)} \\
0^{(k-q) \times q} & Y_{n,k-q} & 0^{(k-q) \times (p-k)} \\
\end{bmatrix} \in R^{k \times p} \text{ if } k < p.
\]

As defined, \(Y_n\) is the diagonal matrix of singular values of \(W_n D_n U_n\), see (16.15).

Proof of Lemma [16.4] The asymptotic distribution of \(n^{1/2}(\bar{g}_n, vec(\bar{D}_n - D_n))\) given in Lemma [16.4] follows from the Lyapunov triangular-array multivariate CLT (using the moment restrictions...
in $F$) and the following:

$$n^{1/2} \text{vec}(\hat{D}_n - D_n) = n^{-1/2} \sum_{i=1}^{n} \text{vec}(G_i - D_n) - \left( \begin{array}{c} \hat{\Gamma}_{1n} \\
\vdots \\
\hat{\Gamma}_{pn} \end{array} \right) \Omega_n^{-1/2} \tilde{g}_n$$

$$= n^{-1/2} \sum_{i=1}^{n} \left[ \text{vec}(G_i - D_n) - \left( \begin{array}{c} E_{F_n} G_{i1} g'_k \\
\vdots \\
E_{F_n} G_{i\ell} g'_{\ell} \end{array} \right) \Omega_{F_n}^{-1} g_i \right] + o_p(1),$$

(25.3)

where the second equality holds by (i) the weak law of large numbers (WLLN) applied to $n^{-1} \sum_{i=1}^{n} G_{ij} g'_k$ for $j = 1, \ldots, p$, $n^{-1} \sum_{i=1}^{n} \text{vec}(G_i)$, and $n^{-1} \sum_{i=1}^{n} g_i g'_k$, (ii) $E_{F_n} g_i = 0^k$, (iii) $h_{5,g} = \lim \Omega_{F_n}$ is pd, and (iv) the CLT, which implies that $n^{1/2} \tilde{g}_n = O_p(1)$.

The limiting covariance matrix between $n^{1/2} \text{vec}(\hat{D}_n - D_n)$ and $n^{1/2} \tilde{g}_n$ is a zero matrix because $E_{F_n} [G_{ij} - E_{F_n} G_{ij} - (E_{F_n} G_{ij} g'_k) \Omega_{F_n}^{-1} g_i] g'_i = 0^{k \times k}$, where $G_{ij}$ denotes the $j$th column of $G_i$. By the CLT, the limiting variance matrix of $n^{1/2} \text{vec}(\hat{D}_n - D_n)$ equals $\lim \text{Var}_{F_n}(\text{vec}(G_i) - (E_{F_n} \text{vec}(G_i) g'_k) \Omega_{F_n}^{-1} g_i) = \lim \Phi_{F_n}^{\text{vec}(G_i)} = \Phi_{h}^{\text{vec}(G_i)}$, see (16.20), and the limit exists because (i) the components of $\Phi_{F_n}^{\text{vec}(G_i)}$ are comprised of $\lambda_{4,F_n}$ and submatrices of $\lambda_{5,F_n}$ and (ii) $\lambda_{s,F_n} \to \lambda_s$ for $s = 4, 5$. By the CLT, the limiting variance matrix of $n^{1/2} \tilde{g}_n$ equals $E_{F_n} g_i g_i' = h_{5,g}$.

The asymptotic distribution of $n^{1/2} W_{F_n} \hat{D}_n U_n T_n$ is obtained as follows. Using (16.13)-(16.15), the singular value decomposition of $W_n D_n U_n$ is $W_n D_n U_n = C_n \Upsilon_n B_n'$. Using this, we get

$$W_n D_n U_n B_{n,q} \Upsilon_{n,q}^{-1} = C_n \Upsilon_n B_{n,q} \Upsilon_{n,q}^{-1} = C_n \left( \begin{array}{l} I_q \\
0_{(p-q)\times q} \end{array} \right) \Upsilon_{n,q}^{-1} = C_n \left( \begin{array}{l} I_q \\
0_{(k-q)\times q} \end{array} \right) = C_{n,q},$$

(25.4)

where the second equality uses $B_{n,q}' B_n = I_p$. Hence, we obtain

$$W_n \hat{D}_n U_n B_{n,q} \Upsilon_{n,q}^{-1} = W_n D_n U_n B_{n,q} \Upsilon_{n,q}^{-1} + W_n n^{1/2} (\hat{D}_n - D_n) U_n B_{n,q} (n^{1/2} \Upsilon_{n,q})^{-1}$$

$$= C_{n,q} + o_p(1) \to_p h_{3,q} = \Delta_{h,q},$$

(25.5)

where the second equality uses (among other things) $n^{1/2} \tau_{j,F_n} \to \infty$ for all $j \leq q$ (by the definition of $q$ in (16.22)). The convergence in (25.5) holds by (16.19), (16.24), and (25.1), and the last equality in (25.5) holds by the definition of $\Delta_{h,q}$ in (16.24).
Using the singular value decomposition of $W_nD_nU_n$ again, we obtain: if $k \geq p$,

$$n^{1/2}W_nD_nU_nB_{n,p-q} = n^{1/2}C_n \mathbf{T}_n B'_nB_{n,p-q} = n^{1/2}C_n \mathbf{T}_n \left( \begin{array}{c} 0^{q \times (p-q)} \\ I_{p-q} \end{array} \right)$$

$$= C_n \begin{pmatrix} 0^{q \times (p-q)} \\ n^{1/2} \mathbf{T}_{n,p-q} \\ 0^{(k-p) \times (p-q)} \end{pmatrix} \rightarrow h_3 \begin{pmatrix} 0^{q \times (p-q)} \\ \text{Diag}\{h_{1,q+1}, \ldots, h_{1,p}\} \\ 0^{(k-p) \times (p-q)} \end{pmatrix} = h_3 h_{1,p-q}^q,$$ (25.6)

where the second equality uses $B'_nB_n = I_p$, the third equality and the convergence hold by (16.19) using the definitions in (16.24) and (25.2) with $k \geq p$, and the last equality holds by the definition of $h_{1,p-q}^q$ in (25.2) with $k \geq p$. Analogously, if $k < p$, we have

$$n^{1/2}W_nD_nU_nB_{n,p-q} = n^{1/2}C_n \mathbf{T}_n \left( \begin{array}{c} 0^{q \times (p-q)} \\ I_{p-q} \end{array} \right) = C_n \begin{pmatrix} 0^{q \times (k-q)} \\ 0^{q \times (p-k)} \\ n^{1/2} \mathbf{T}_{n,k-q} \\ 0^{(k-q) \times (p-k)} \end{pmatrix}$$

$$\rightarrow h_3 \begin{pmatrix} 0^{q \times (k-q)} \\ \text{Diag}\{h_{1,q+1}, \ldots, h_{1,k}\} \\ 0^{(k-q) \times (p-k)} \end{pmatrix} = h_3 h_{1,p-q}^q,$$ (25.7)

where the third equality holds by (25.2) with $k < p$ and the last equality holds by the definition of $h_{1,p-q}^q$ in (16.24) with $k < p$.

Using (25.6), (25.7), and $n^{1/2}(\tilde{g}_n, \tilde{D}_n - D_n) \rightarrow_d (\overline{g}_h, \overline{D}_h)$, we get

$$n^{1/2}W_n\tilde{D}_nU_nB_{n,p-q} = n^{1/2}W_nD_nU_nB_{n,p-q} + W_n n^{1/2}(\tilde{D}_n - D_n)U_nB_{n,p-q}$$

$$\rightarrow_d h_3 h_{1,p-q}^q + h_7 \overline{D}_h h_{81} h_{2,p-q} = \overline{\alpha}_{h,p-q},$$ (25.8)

where $B_{n,p-q} \rightarrow h_{2,p-q}$, $W_n \rightarrow h_7$, and $U_n \rightarrow h_{81}$, and the last equality holds by the definition of $\overline{\alpha}_{h,p-q}$ in (16.24).

Equations (25.5) and (25.8) combine to establish

$$n^{1/2}W_n\tilde{D}_nU_nT_n = n^{1/2}W_n\tilde{D}_nU_nB_nS_n = (W_n\tilde{D}_nU_nB_{n,q} \mathbf{T}_{n,q}^{-1}, n^{1/2}W_n\tilde{D}_nU_nB_{n,p-q})$$

$$\rightarrow_d (\overline{\alpha}_{h,q}, \overline{\alpha}_{h,p-q}) = \overline{\alpha}_h$$ (25.9)

using the definition of $S_n$ in (16.23). This completes the proof of the convergence result of Lemma (16.3).

Parts (a) and (b) of the lemma hold by the definitions of $(\overline{g}_h, \overline{D}_h)$ and $\overline{\alpha}_h$. The independence of $(\overline{D}_h, \overline{\alpha}_h)$ and $\overline{g}_h$, stated in part (c) of the lemma, holds by the independence of $\overline{g}_h$ and $\overline{D}_h$ (which
follows from ([16.21]), and part (b) of the lemma. Part (d) is proved by replacing \( n \) by \( w_n \) in the proofs above. \( \square \)

**Proposition 16.5.** Suppose Assumption WU holds for some non-empty parameter space \( \Lambda_* \subset \Lambda_{WU} \). Under all sequences \( \{\lambda_{n,h} : n \geq 1\} \) with \( \lambda_{n,h} \in \Lambda_* \),

(a) \( \kappa_{jn} \to_p \infty \) for all \( j \leq q \),

(b) the (ordered) vector of the smallest \( p-q \) eigenvalues of \( n\hat U_n' \hat D_n' \hat W_n' \hat D_n \hat W_n, \) i.e., \( (\kappa_{(q+1)n}, ..., \kappa_{pn})' \), converges in distribution to the (ordered) \( p-q \) vector of the eigenvalues of \( \Sigma_h p-q h_{3,k-q} h'_{3,k-q} \times \Delta_{h,p-q} \in \mathbb{R}^{(p-q)\times(p-q)} \),

(c) the convergence in parts (a) and (b) holds jointly with the convergence in Lemma 16.4 and

(d) under all subsequences \( \{w_n\} \) and all sequences \( \{\lambda_{w_n,h} : n \geq 1\} \) with \( \lambda_{w_n,h} \in \Lambda_* \), the results in parts (a)-(c) hold with \( n \) replaced with \( w_n \).

**Proof of Proposition 16.5.** For the case where \( k \geq p \), Proposition 16.5 is the same as Theorem 10.4(c)-(f) given in the SM to AG1, which is proved in Section 17 in the SM to AG1. For brevity, we only describe the changes that need to be made to that proof to cover the case where \( k < p \).

Note that the proof of Theorem 10.4(c)-(f) in AG1 is similar to, but simpler than, the proof of Theorem 16.6, which is given in Section 28 below.

In the second line of the proof of Lemma 17.1 in the SM to AG1, \( p \) needs to be replaced by \( \min\{k,p\} \) three times.

In the fourth line of (17.3) in the SM to AG1, the \( k \times p \) matrix that contains six submatrices needs to be replaced by the following matrix when \( k < p \):

\[
\begin{bmatrix}
    h^*_{6,r_5} + o(1) & 0^{r_1\times (k-r_1)} & 0^{r_1\times (p-k)} \\
    0^{(k-r_1)\times r_1} & O(\tau_{r_2F_n}/\tau_{r_1F_n})^{(k-r_1)\times (k-r_1)} & 0^{(k-r_1)\times (p-k)}
\end{bmatrix} \in \mathbb{R}^{k\times p}, \quad (25.10)
\]

where \( r_5^* \) is defined as in the proof of Lemma 17.1 in the SM to AG1.

In the first line of (17.22) in the SM to AG1, the \( k \times (p-r_{g-1}^*) \) matrix that contains three submatrices needs to be replaced by the following matrix when \( k < p \):

\[
\begin{bmatrix}
    0^{r_{g-1}\times (k-r_{g-1}^*)} & 0^{r_{g-1}\times (p-k)} \\
    \text{Diag}\{\tau_{r_gF_n}, ..., \tau_{kF_n}\}/\tau_{r_gF_n} & 0^{(k-r_{g-1}^*)\times (p-k)}
\end{bmatrix} \in \mathbb{R}^{k\times (p-r_{g-1}^*)}, \quad (25.11)
\]

The limit of this matrix as \( n \to \infty \) equals the matrix given in the second line of (17.22) that contains three submatrices. Thus, the limit of the matrix on the first line of (17.22) is the same for the cases where \( k \geq p \) and \( k < p \).

In the third line of (17.25) in the SM to AG1, the second matrix that contains three submatrices
(which is a \( k \times (p - r_g^0) \) matrix) is the same as the matrix in the first line of (17.22) in the SM to AG1, but with \( r_g^0 \) in place of \( r_g^{0-1} \) (using \( r_{g+1} = r_g^0 + 1 \) and \( r_g = r_g^{0-1} + 1 \)). When \( k < p \), this matrix needs to be changed just as the matrix in the first line of (17.22) is changed in (25.11), but with \( r_g^0 \) in place of \( r_g^{0-1} \).

No other changes are needed. \( \square \)

26 Proof of Theorem 16.6

Theorem 16.6. Suppose Assumption WU holds for some non-empty parameter space \( \Lambda_s \subset \Lambda_{WU} \). Under all sequences \( \{\lambda_n, h : n \geq 1\} \) with \( \lambda_n, h \in \Lambda_s \),

\[
QLR_{WU,n} \rightarrow d \mathcal{F}_h^{-1} h_{5,g}^{-1} - \lambda_{\min}((\mathcal{X}_{h,p-q}, h_{5,g}^{-1/2} \mathcal{F}_h) h_{3,k-q} h_{3,k-q} (\mathcal{X}_{h,p-q}, h_{5,g}^{-1/2} \mathcal{F}_h))
\]

and the convergence holds jointly with the convergence in Lemma 16.4 and Proposition 16.5. When \( q = p \) (which can only hold if \( k \geq p \) because \( q \leq \min\{k, p\} \)), \( \mathcal{X}_{h,p-q} \) does not appear in the limit random variable and the limit random variable reduces to \( (h_{5,g}^{-1/2} \mathcal{F}_h) h_{3,p} h_{3,p} h_{5,g}^{-1/2} \mathcal{F}_h \sim \chi^2_p \). When \( q = k \) (which can only hold if \( k \leq p \)), the \( \lambda_{\min}(\cdot) \) expression does not appear in the limit random variable and the limit random variable reduces to \( \mathcal{F}_h h_{5,g}^{-1} \mathcal{F}_h \sim \chi^2_k \). When \( k \leq p \) and \( q < k \), the \( \lambda_{\min}(\cdot) \) expression equals zero and the limit random variable reduces to \( \mathcal{F}_h h_{5,g}^{-1} \mathcal{F}_h \sim \chi^2_k \). Under all subsequences \( \{w_n\} \) and all sequences \( \{\lambda_{w,n,h} : n \geq 1\} \) with \( \lambda_{w,n,h} \in \Lambda_s \), the same results hold with \( n \) replaced with \( w_n \).

The proof of Theorem 16.6 uses the approach in Johansen (1991, pp. 1569-1571) and Robin and Smith (2000, pp. 172-173). In these papers, asymptotic results are established under a fixed true distribution under which certain population eigenvalues are either positive or zero. Here we need to deal with drifting sequences of distributions under which these population eigenvalues may be positive or zero for any given \( n \), but the positive ones may drift to zero as \( n \rightarrow \infty \), possibly at different rates. This complicates the proof considerably. For example, the rate of convergence result of Lemma 26.1(b) below is needed in the present context, but not in the fixed distribution scenario considered in Johansen (1991) and Robin and Smith (2000).
The proof uses the notation given in (25.1) and (25.2) above. The following definitions are used:

\[
\hat{D}^+_n := (\hat{D}_n, \hat{W}_n^{-1}\hat{\Omega}_n^{-1/2}\hat{g}_n) \in \mathbb{R}^{k \times (p+1)}, \quad \hat{U}^+_n := \begin{bmatrix} \hat{U}_n & 0^{p \times 1} \\ 0^{1 \times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1) \times (p+1)},
\]

\[
U^+_n := \begin{bmatrix} U_n & 0^{p \times 1} \\ 0^{1 \times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1) \times (p+1)}, \quad h^{81} := \begin{bmatrix} h_{81} & 0^{p \times 1} \\ 0^{1 \times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1) \times (p+1)},
\]

\[
B^+_n := \begin{bmatrix} B_n & 0^{p \times 1} \\ 0^{1 \times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1) \times (p+1)},
\]

\[
B^+_n = (B^+_{n,q}, B^+_{n,p+1-q}) \text{ for } B^+_{n,q} \in \mathbb{R}^{(p+1) \times q} \text{ and } B^+_{n,p+1-q} \in \mathbb{R}^{(p+1) \times (p+1-q)}, \quad (26.1)
\]

\[
D^+_n := (D_n, 0^k) \in \mathbb{R}^{k \times (p+1)}, \quad \Upsilon^+_n := (\Upsilon_n, 0^k) \in \mathbb{R}^{k \times (p+1)},
\]

\[
S^+_n := Diag\{ (n^{1/2}r_1F_n)^{-1}, ..., (n^{1/2}r_qF_n)^{-1}, 1, ..., 1 \} = \begin{bmatrix} S_n & 0^{p \times 1} \\ 0^{1 \times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1) \times (p+1)},
\]

where \( \hat{g}_n \) and \( \hat{\Omega}_n \) are defined in (4.1) with \( \theta = \theta_0 \), \( \hat{D}_n \) is defined in (5.2) with \( \theta = \theta_0 \), \( \hat{W}_n, \hat{U}_n, U_n \) \((= U_{F_n})\), and \( W_n (= W_{F_n}) \) are defined in (16.4), \( h^{81} \) is defined in (16.24), \( B_n (= B_{F_n}) \) is defined in (16.13), \( D_n \) is defined in (25.1), \( \Upsilon_n \) is defined in (25.2), and \( S_n \) is defined in (16.23).

Let \( \hat{\kappa}^+_jn \) denote the \( j \)th eigenvalue of \( n\hat{U}_n^t\hat{D}_n^+\hat{W}_n^t\hat{W}_n\hat{D}_n^+\hat{U}_n^+ \), \( \forall j = 1, ..., p+1 \), (26.2)

ordered to be nonincreasing in \( j \). We have

\[
\hat{W}_n\hat{D}_n^+\hat{U}_n^+ = (\hat{W}_n\hat{D}_n\hat{U}_n, \hat{\Omega}_n^{-1/2}\hat{g}_n) \quad (26.3)
\]

\[
\lambda_{\min}(n(\hat{W}_n\hat{D}_n\hat{U}_n, \hat{\Omega}_n^{-1/2}\hat{g}_n)(\hat{W}_n\hat{D}_n\hat{U}_n, \hat{\Omega}_n^{-1/2}\hat{g}_n))) = \lambda_{\min}(n\hat{U}_n^t\hat{D}_n^t\hat{W}_n^t\hat{W}_n\hat{D}_n^+\hat{U}_n^+) = \hat{\kappa}^+_jn. \quad (26.4)
\]

The proof of Theorem 16.6 uses the following rate of convergence lemma, which is analogous to Lemma 17.1 in Section 17 of the SM to AG1.

**Lemma 26.1** Suppose Assumption WU holds for some non-empty parameter space \( \Lambda_* \subset \Lambda_{WU} \). Under all sequences \( \{\lambda_{n,h} : n \geq 1\} \) with \( \lambda_{n,h} \in \Lambda_* \) for which \( q \) defined in (16.22) satisfies \( q \geq 1 \), we have (a) \( \hat{\kappa}^+_jn \to_p \infty \) for \( j = 1, ..., q \) and (b) \( \hat{\kappa}^+_jn = o_p((n^{1/2}\tau_{\ell F_n})^2) \) for all \( \ell \leq q \) and \( j = q+1, ..., p+1 \). Under all subsequences \( \{w_n\} \) and all sequences \( \{\lambda_{w_{n,h}} : n \geq 1\} \) with \( \lambda_{w_{n,h}} \in \Lambda_* \), the same result

\(^{65}\)In (26.3), we write \( (\hat{W}_n\hat{D}_n\hat{U}_n, \hat{\Omega}_n^{-1/2}\hat{g}_n) \), whereas we write its analogue \((\hat{\Omega}_n^{-1/2}\hat{g}_n, \hat{D}_n^+\hat{u}_n) \) in (5.7) with its columns in the reverse order. Both ways give the same value for the minimum eigenvalue of the inner product of the matrix with itself, which is the statistic of interest. We use the order \((\hat{\Omega}_n^{-1/2}\hat{g}_n, \hat{D}_n^+) \) in AG2 because it is consistent with the order in Moreira (2003) and Andrews, Moreira, and Stock (2006). We use the order \((\hat{W}_n\hat{D}_n\hat{U}_n, \hat{\Omega}_n^{-1/2}\hat{g}_n) \) here (and elsewhere in the SM) because it has significant notational advantages in the proofs, especially in the proof of Theorem 16.6 in this Section.
holds with \( n \) replaced with \( w_n \).

**Proof of Theorem 16.6.** We have \( n^{1/2} \bar{g}_n \to_d \bar{g}_h \) (by Lemma 16.4) and \( \hat{\Omega}_n^{-1/2} \to_p h_{5,g}^{-1/2} \) (because \( \hat{\Omega}_n - \Omega_{F_n} \to 0^{k \times k} \) by the WLLN, \( \Omega_{F_n} \to h_{5,g} \), and \( h_{5,g} \) is pd). In consequence, \( AR_n \to_d \bar{g}_h^2 h_{5,g} \bar{g}_h \).

Given this, the definition of \( Q L R_n \) in (16.3), and (26.3), to prove the convergence result in Theorem 16.6 it suffices to show that

\[
\lambda_{\min}(n \hat{U}_n^+ \hat{D}_n^+ \hat{W}_n \hat{D}_n^+ \hat{U}_n^+) \to_d \lambda_{\min}(\{\hat{\Omega}_{h,p-q}, h_{5,g}^{-1/2} \bar{g}_h\})^{h_{3,k-q}} h_{3,k-q}^{-1}(\hat{\Omega}_{h,p-q}, h_{5,g}^{-1/2} \bar{g}_h)).
\]

Now we establish (26.4). The eigenvalues \( \{\hat{\kappa}_j^+ : j \leq p+1\} \) of \( n \hat{U}_n^+ \hat{D}_n^+ \hat{W}_n \hat{D}_n^+ \hat{U}_n^+ \) are the ordered solutions to the determinantal equation \( n \hat{U}_n^+ \hat{D}_n^+ \hat{W}_n \hat{D}_n^+ \hat{U}_n^+ - \kappa I_{p+1} = 0 \). Equivalently, with probability that goes to one (wp\( \to 1 \)), they are the solutions to

\[
|Q_n^+(\kappa)| = 0, \quad Q_n^+(\kappa) := n S_n^+ B_n^+ U_n^+ \hat{D}_n^+ \hat{W}_n \hat{D}_n^+ U_n^+ B_n^+ S_n^+ - \kappa S_n^+ B_n^+ U_n^+ (\hat{U}_n^+)^{-1}(\hat{U}_n^+)^{-1} U_n^+ B_n^+ S_n^+;
\]

because \( |S_n^+| > 0, |B_n^+| > 0, |U_n^+| > 0 \) and \( |\hat{U}_n^+| > 0 \) wp\( \to 1 \). Thus, \( \lambda_{\min}(n \hat{U}_n^+ \hat{D}_n^+ \hat{W}_n \hat{D}_n^+ \hat{U}_n^+) \) equals the smallest solution, \( \hat{\kappa}_j^+ \), to \( |Q_n^+(\kappa)| = 0 \) wp\( \to 1 \). (For simplicity, we omit the qualifier wp\( \to 1 \) that applies to several statements below.)

We write \( Q_n^+(\kappa) \) in partitioned form using

\[
B_n^+ S_n^+ = (B_{n,q}^+ S_{n,q}, B_{n,p+1-q}^+), \quad \text{where} \quad S_{n,q} := \text{Diag}\{(n^{1/2} \tau_{1F_n})^{-1}, ..., (n^{1/2} \tau_{qF_n})^{-1}\} \in R^{q \times q}.
\]

The convergence result of Lemma 16.4 for \( n^{1/2} W_n \hat{D}_n U_n T_n = n^{1/2} W_n \hat{D}_n U_n B_n S_n \) can be written as

\[
n^{1/2} W_n \hat{D}_n^+ U_n^+ B_{n,q} S_{n,q} = n^{1/2} W_n \hat{D}_n U_n B_{n,q} S_{n,q} \to_p \bar{\Omega}_{h,q} := h_{3,q} \quad \text{and} \quad
\]

\[
n^{1/2} W_n \hat{D}_n^+ U_n^+ B_{n,p+1-q} = n^{1/2} W_n (\hat{D}_n^+, \hat{W}_n^{-1} \hat{\Omega}_n^{-1/2} \bar{g}_n) U_n^+ B_{n,p+1-q}^+
\]

\[
= n^{1/2} (W_n \hat{D}_n U_n B_{n,p-q}, W_n \hat{W}_n^{-1} \hat{\Omega}_n^{-1/2} \bar{g}_n)
\]

\[
\to_d (\hat{\Omega}_{h,p-q}, h_{5,g}^{-1/2} \bar{g}_h),
\]

where \( \bar{\Omega}_{h,q} \) and \( \hat{\Omega}_{h,p-q} \) are defined in (16.24), \( B_{n,p-q} \) is defined in (25.1), and the convergence in distribution uses \( \hat{W}_n W_n^{-1} \to_p I_k \) by (26.8).

We have

\[
\hat{W}_n W_n^{-1} \to_p I_k \quad \text{and} \quad \hat{U}_n^+ (U_n^+)^{-1} \to_p I_{p+1}.
\]

70
because $\hat{W}_n \rightarrow_p h_{71} := \lim W_n$ (by Assumption WU(a) and (c)), $\hat{U}_n^+ \rightarrow_p h_{81}^+ := \lim U_n^+$ (by Assumption WU(b) and (c)), and $h_{71}$ and $h_{81}^+$ are pd (by the conditions in $\mathcal{F}_{WU}$).

By (26.5)-(26.8), we have

$$Q_n^+(\kappa) = \begin{bmatrix}
I_q + o_p(1) & h_{3,q}^n n^{1/2} W_n^0 D_n^+ U_n^+ B_{n,p+1-q}^+ + o_p(1) \\
n^{1/2} B_n^+ n^{p+1-q} U_n^+ D_n^+ W_n h_{3,q}^n + o_p(1) & n^{1/2} B_n^+ n^{q+1} U_n^+ D_n^+ W_n W_n^{1/2} D_n^+ U_n^+ B_{n,p+1-q}^+ + o_p(1)
\end{bmatrix},$$

$$\hat{A}_n^+ = \begin{bmatrix}
A_{1n}^+ & A_{2n}^+ \\
A_{3n}^+ & A_{3n}^+
\end{bmatrix} := B_n^+ U_n^+ (\hat{U}_n^+)^{-1} (\hat{U}_n^+)^{-1} U_n^+ B_n^+ - I_{p+1} = o_p(1)$$

for $A_{1n}^+ \in R^{q \times q}$, $A_{2n}^+ \in R^{q \times (p+1-q)}$, and $A_{3n}^+ \in R^{(p+1-q) \times (p+1-q)}$, and the first equality uses $\hat{\Sigma}_{h,q} := h_{3,q}^n h_{3,q}^n = q C_{n,q}^r C_{n,q} = I_q$ (by (16.14), (16.16), (16.19), and (16.24)). Note that $A_{jn}^+$ and $A_{jn}^+$ (defined in (26.19) below) are not the same in general for $j = 1, 2, 3$ because their dimensions differ. For example, $A_{1n}^+ \in R^{q \times q}$, whereas $A_{1n}^+ \in R^{r_1 \times r_1}$, where $r_1$ is defined as in the proof of Lemma 17.1 in the SM to AG1.

If $q = 0$, then $B_n^+ = B_{n,p+1-q}^+$ and

$$n B_n^+ U_n^+ D_n^+ W_n^0 D_n^+ \overset{d}{\rightarrow} (\hat{\Sigma}_{h,p-q} h_{5,g}^{-1/2} \hat{g}_h)^{1/2} (\hat{\Sigma}_{h,p-q} h_{5,g}^{-1/2} \hat{g}_h),$$

where the convergence holds by (26.7) and (26.8) and $\hat{\Sigma}_{h,p-q}$ is defined as in (16.24) with $q = 0$.

The smallest eigenvalue of a matrix is a continuous function of the matrix (by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38)). Hence, the smallest eigenvalue of $n B_n^+ U_n^+ D_n^+ W_n^0 D_n^+ \overset{d}{\rightarrow} (\hat{\Sigma}_{h,p-q} h_{5,g}^{-1/2} \hat{g}_h)^{1/2} (\hat{\Sigma}_{h,p-q} h_{5,g}^{-1/2} \hat{g}_h)$ converges in distribution to the smallest eigenvalue of $h_{3,k-q} h_{3,k-q}^t (\hat{\Sigma}_{h,p-q} h_{5,g}^{-1/2} \hat{g}_h)$ (using $h_{3,k-q} h_{3,k-q}^t = I_k$ when $q = 0$), which proves (26.4) when $q = 0$.

In the remainder of the proof of (26.4), we assume $q \geq 1$, which is the remaining case to be considered in the proof of (26.4). The formula for the determinant of a partitioned matrix and
By Lemma 26.1(b) (which applies for $q \geq 1$), for $j = q + 1, \ldots, p + 1$, and $A_{1n}^+ = o_p(1)$ (by (26.9)), we have $\hat{\kappa}_{jn}^+ S_{n,q}^2 = o_p(1)$ and $\hat{\kappa}_{jn}^+ S_{n,q} A_{1n}^+ S_{n,q} = o_p(1)$. Thus, for $j = q + 1, \ldots, p + 1$,

$$Q_{1n}^+ (\hat{\kappa}_{jn}^+) = I_q + o_p(1) - \hat{\kappa}_{jn}^+ S_{n,q}^2 - \hat{\kappa}_{jn}^+ S_{n,q} A_{1n}^+ S_{n,q} = I_q + o_p(1). \tag{26.12}$$

By (26.5) and (26.11), $|Q_{1n}^+ (\hat{\kappa}_{jn}^+)| = |Q_{1n}^+ (\hat{\kappa}_{jn}^+) - Q_{2n}^+ (\hat{\kappa}_{jn}^+)| = 0$ for $j = 1, \ldots, p + 1$. By (26.12), $|Q_{1n}^+ (\hat{\kappa}_{jn}^+)| \neq 0$ for $j = q + 1, \ldots, p + 1$ wp→1. Hence, wp→1,

$$|Q_{2n}^+ (\hat{\kappa}_{jn}^+)| = 0 \text{ for } j = q + 1, \ldots, p + 1. \tag{26.13}$$

Now we plug in $\hat{\kappa}_{jn}^+$ for $j = q + 1, \ldots, p + 1$ into $Q_{2n}^+(\kappa)$ in (26.11) and use (26.12). We have

$$Q_{2n}^+(\hat{\kappa}_{jn}^+) = nB_{n,p+1-q}^+ U^+ \hat{D}_n^+ W_n^+ W_n^+ \hat{D}_n^+ U^+ B_{n,p+1-q}^+ + o_p(1)$$

$$- [n^{1/2} B_{n,p+1-q}^+ U^+ \hat{D}_n^+ W_n^+ h_{n,q} + o_p(1)] (I_q + o_p(1)) [h_{n,q} n^{1/2} W_n^+ \hat{D}_n^+ U^+ B_{n,p+1-q}^+ + o_p(1)]$$

$$- \hat{\kappa}_{jn}^+ (I_{p+1-q} + A_{jn}^+ - (n^{1/2} B_{n,p+1-q}^+ U^+ \hat{D}_n^+ W_n^+ h_{n,q} + o_p(1)) (I_q + o_p(1)) S_{n,q} A_{2n}^+$$

$$- A_{2n}^+ S_{n,q} (I_q + o_p(1)) (h_{n,q} n^{1/2} W_n^+ \hat{D}_n^+ U^+ B_{n,p+1-q}^+ + o_p(1))$$

$$+ \hat{\kappa}_{jn}^+ A_{2n}^+ S_{n,q} (I_q + o_p(1)) S_{n,q} A_{2n}^+. \tag{26.14}$$

The term in square brackets on the last three lines of (26.14) that multiplies $\hat{\kappa}_{jn}^+$ equals

$$I_{p+1-q} + o_p(1), \tag{26.15}$$

because $A_{3n}^+ = o_p(1)$ (by (26.9)), $n^{1/2} W_n^+ \hat{D}_n^+ U^+ B_{n,p+1-q}^+ = O_p(1)$ (by (26.7)), $S_{n,q} = o(1)$ (by the definitions of $q$ and $S_{n,q}$ in (16.22) and (26.6), respectively, and $h_{n,j} := \lim q n^{1/2} \tau_{jF_n}$), $A_{2n}^+ = o_p(1)$ (by (26.9)), and $\hat{\kappa}_{jn}^+ A_{2n}^+ S_{n,q} (I_q + o_p(1)) S_{n,q} A_{2n}^+ = A_{2n}^+ \hat{\kappa}_{jn}^+ S_{n,q}^2 A_{2n}^+ + A_{2n}^+ \hat{\kappa}_{jn}^+ S_{n,q} o_p(1) S_{n,q} A_{2n}^+ = o_p(1)$
(using \( \tilde{\kappa}_{jn}^+ S_{n,q}^2 = o_p(1) \) and \( A_{2n}^+ = o_p(1) \)).

Equations (26.14) and (26.15) give

\[
Q_{2n}(\tilde{\kappa}_{jn}) = n^{1/2} B_{n,p+1-q} U_n^{1/2} \tilde{D} \tilde{W}_n [I_k - h_{3,q} h_{3,q}'] n^{1/2} W_n \tilde{D} n^{1/2} U_n^+ B_{n,p+1-q} + o_p(1) - \tilde{\kappa}_{jn}^+ [I_{p+1-q} + o_p(1)]
\]

\[
= n^{1/2} B_{n,p+1-q} U_n^{1/2} \tilde{D} \tilde{W}_n h_{3,k-q} h_{3,k-q} n^{1/2} W_n \tilde{D} n^{1/2} U_n^+ B_{n,p+1-q} + o_p(1) - \tilde{\kappa}_{jn}^+ [I_{p+1-q} + o_p(1)]
\]

\[
:= M_{n,p+1-q}^+ - \tilde{\kappa}_{jn}^+ [I_{p+1-q} + o_p(1)], \tag{26.16}
\]

where the second equality uses \( I_k = h_3 h_3' = h_{3,q} h_{3,q}' + h_{3,k-q} h_{3,k-q}' \) (because \( h_3 = \lim C_n \) is an orthogonal matrix) and the last line defines the \((p + 1 - q) \times (p + 1 - q)\) matrix \( M_{n,p+1-q}^+ \).

Equations (26.13) and (26.16) imply that \( \{\tilde{\kappa}_{jn}^+ : j = q + 1, ..., p + 1\} \) are the \( p + 1 - q \) eigenvalues of the matrix

\[
M_{n,p+1-q}^+ := [I_{p+1-q} + o_p(1)]^{-1/2} M_{n,p+1-q}^+ [I_{p+1-q} + o_p(1)]^{-1/2} \tag{26.17}
\]

by pre- and post-multiplying the quantities in (26.16) by the rhs quantity \([I_{p+1-q} + o_p(1)]^{-1/2}\) in (26.16). By (26.7),

\[
M_{n,p+1-q}^+ \rightarrow_d (\Delta_{h,p-q}, h_{5,g}^{-1/2} \tilde{g}_h)' h_{3,k-q} h_{3,k-q} (\Delta_{h,p-q}, h_{5,g}^{-1/2} \tilde{g}_h). \tag{26.18}
\]

The vector (ordered) eigenvalues of a matrix is a continuous function of the matrix (by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38)). By (26.18), the matrix \( M_{n,p+1-q}^+ \) converges in distribution. In consequence, by the CMT, the vector of eigenvalues of \( M_{n,p+1-q}^+ \), viz., \( \{\tilde{\kappa}_{jn}^+ : j = q + 1, ..., p + 1\} \), converges in distribution to the vector of eigenvalues of the limit matrix \((\Delta_{h,p-q}, h_{5,g}^{-1/2} \tilde{g}_h)' h_{3,k-q} h_{3,k-q} (\Delta_{h,p-q}, h_{5,g}^{-1/2} \tilde{g}_h)\). Hence, \( \lambda_{\min} (n^{1/2} \tilde{D} \tilde{W}_n \tilde{D} n^{1/2} \tilde{W}_n \tilde{D} n^{1/2} \tilde{U}_n) \), which equals the smallest eigenvalue, \( \tilde{\kappa}_{(p+1)n}^+ \), converges in distribution to the smallest eigenvalue of \((\Delta_{h,p-q}, h_{5,g}^{-1/2} \tilde{g}_h)' h_{3,k-q} h_{3,k-q} (\Delta_{h,p-q}, h_{5,g}^{-1/2} \tilde{g}_h)\), which completes the proof of (26.4).

The previous paragraph proves Comment (v) to Theorem [16.6] for the smallest \( p + 1 - q \) eigenvalues of \( n (\tilde{W}_n \tilde{D}_n \tilde{U}_n, \tilde{\Omega}_n^{-1/2} \tilde{g}_n)' (\tilde{W}_n \tilde{D}_n \tilde{U}_n, \tilde{\Omega}_n^{-1/2} \tilde{g}_n) \). In addition, by Lemma [26.1] (a), the largest \( q \) eigenvalues of this matrix diverge to infinity in probability, which completes the proof of Comment (v) to Theorem [16.6].

When \( q = p \), the third and fourth lines in (26.7) become \( n^{1/2} W_n \tilde{W}_n^{-1/2} \tilde{\Omega}_n^{-1/2} \tilde{g}_h \) and \( h_{5,g}^{-1/2} \tilde{g}_h \), respectively, i.e., \( n^{1/2} W_n \tilde{D}_n U_n B_{n,p-q} \) and \( \Delta_{h,p-q} \) drop out (because \( U_n^+ B_{n,p+1-q}^+ = (0^p, 1)' \) in this case). In consequence, the limit in (26.18) becomes \((h_{5,g}^{-1/2} \tilde{g}_h)' h_{3,k-q} h_{3,k-q} h_{5,g}^{-1/2} \tilde{g}_h \), which has a \( \chi^2_{k-p} \) distribution (because \( h_{5,g}^{-1/2} \tilde{g}_h \sim N(0^p, I_k) \), \( h_3 = (h_{3,q}, h_{3,k-q}) \in R^{k \times k} \) is an orthogonal matrix, and \( h_{3,k-q} \) has \( k - p \) columns when \( q = p \).
The convergence in Theorem 16.6 holds jointly with that in Lemma 16.4 and Proposition 16.5 because the results in Proposition 16.5 and Theorem 16.6 just rely on the convergence in distribution of \( n^{1/2}W_n\widehat{D}_nU_nT_n \), which is part of Lemma 16.4.

When \( q = k \), the \( \lambda_{\min}(\cdot) \) expression does not appear in the limit random variable in the statement of Theorem 16.6 because, in the second line of (26.16) above, the term \( I_k - h_{3,q}h_{3,q}^t \) equals 0, which implies that \( \frac{M_{n,p+1}}{n} = 0 \) or \( \frac{M_{n,p+1}}{n} = 0 \) in (26.17) and (26.18).

When \( k \leq p \) and \( q < k \), the \( \lambda_{\min}(\cdot) \) expression (in the limit random variable in the statement of Theorem 16.6) equals zero because \( h_{3,k-q}^t(\Delta_{h,p-q},h_{5,q}^{-1/2}g_h) \) is a \((k-q) \times (p+1-q)\) matrix, which has fewer rows than columns when \( k < p \).

The convergence in Theorem 16.6 holds for a subsequence \( \{w_n : n \geq 1\} \) of \( \{n\} \) by the same proof as given above with \( n \) replaced by \( w_n \). □

**Proof of Lemma 26.1** The proof of Lemma 26.1 is the same as the proof of Lemma 17.1 in Section 17 in the SM to AG1, but with \( p \) replaced by \( p+1 \) (so \( p+1 \) is always at least two), with \( \tau_{(p+1)}F_n := 0 \), with \( h_{6,p} := \lim (\tau_{(p+1)}F_n)/\tau_{p}F_n = 0 \) (using 0/0 := 0), and with \( \widehat{D}_n, \widehat{U}_n, B_n, \kappa_{jn}, \widehat{\Lambda}_n, D_n, U_n, h_{81}, \gamma_n, B_{n,r_1}, \) and \( B_{n,p-r_1} \) replaced by \( \widehat{D}_n, \widehat{U}_n, B_n, \kappa_{jn}, \widehat{\Lambda}_n, D_n, U_n, h_{81}, \gamma_n, B_{n,r_1} \), and \( B_{n,p+1-r_1} \), respectively, where

\[
\widehat{\Lambda}_n^+ = \begin{bmatrix} \widehat{\Lambda}_{1n}^+ & \widehat{\Lambda}_{2n}^+ \\ \widehat{\Lambda}_{2n}^{+t} & \widehat{\Lambda}_{3n}^+ \end{bmatrix} := (B_n^+)'(U_n^+)'(\widehat{U}_n^+)^{-1}(\widehat{U}_n^+) - I_{2n+1} \tag{26.19}
\]

where \( \widehat{\Lambda}_{1n}^+ \in R^{q \times r_1^2}, \widehat{\Lambda}_{2n}^+ \in R^{r_1 \times (p+1-r_1)}, \widehat{\Lambda}_{3n}^+ \in R^{(p+1-r_1) \times (p+1-r_1)}, \) and \( r_1^2 \) is defined as in the proof of Lemma 17.1 in the SM to AG1. Note that the quantities \( \widehat{\Lambda}_{\ell n} \) for \( \ell = 1, 2, 3 \), which depend on \( \widehat{\Lambda}_n \) (see (17.2) in the SM to AG1), differ between the two proofs (because \( \widehat{\Lambda}_n \) differs from \( \widehat{\Lambda}_n^+ \)). Similarly, the quantities \( \Phi_n \) (defined in (17.8) in the SM to AG1), \( \tilde{\Xi}_{\ell n}(\kappa) \) for \( \ell = 1, 2, 3 \) (defined in (17.9) in the SM to AG1), and \( \widehat{\Lambda}_{j2n} \) (defined in (17.12) in the SM to AG1) differ between the two proofs (because the quantities on which they depend differ between the two proofs).

The following quantities are the same in both proofs: \( \{\tau_{jF_n} : j \leq p\}, \{h_{6,j} : j \leq p-1\}, G_h, \{r_j : j \leq G_h\}, \{r_j^\circ : j \leq G_h\}, h_{6,r_1^2}, \widehat{W}_n, h_{71}, C_n, \) and \( h_{3} \). Note that the first \( p \) singular values of \( W_nD_nU_n \) (i.e., \( \{\tau_{jF_n} : j \leq p\} \)) and the first \( p \) singular values of \( W_nD_nU_n^+ \) are the same. This holds because \( \tau_{jF_n} = \kappa_{jF_n}^{1/2} \), where \( \kappa_{jF_n} \) is the \( j \)th eigenvalue of \( W_nD_nU_nU_n^+D_nW_n \), \( W_nD_nU_n^+W_n^+ = W_n(D_n, 0^k)U_n^+ = (W_nD_nU_n, 0^k) \), and hence, \( W_nD_nU_nU_n^+D_nW_n = W_nD_nU_nU_n^+D_nW_n \).

The second equality in (17.3) in the SM to AG1, which states that \( W_nD_nU_nB_n = C_n\gamma_n \), is a key equality in the proof of Lemma 17.1 in the SM to AG1. The analogue in the proof of the
current lemma is
\[ W_n D_n^+ U_n^+ B_n^+ = (W_n D_n, 0^k) \left[ \begin{array}{c} U_n B_n \\ 0^{p \times 1} \end{array} \right] = (W_n D_n U_n B_n, 0^k) = (C_n, 0^k) = C_n \Upsilon_n^+. \]

(26.20)

Hence, this part of the proof goes through when \( D_n, U_n, B_n, \) and \( \Upsilon_n \) are replaced by \( D_n^+, U_n^+, B_n^+, \) and \( \Upsilon_n^+ \), respectively. \( \Box \)

27 Proofs of the Asymptotic Size Results

In this section we prove Theorem 16.1 stated in Section 16.1.

Theorem 16.1 is proved first for the CQLR and CQLR\(_P\) tests and CS’s. For these test results, we actually prove a more general result that applies to a CQLR test statistic that is defined as the CQLR test statistic is defined in Section 5, but with the weight matrices \((\hat{\Omega}_n^{-1/2}, \hat{L}_n^{1/2})\) replaced by any matrices \((\hat{W}_n, \hat{U}_n)\) that satisfy Assumption WU for some parameter space \( \Lambda_* \subset \Lambda_{WU} \) (stated in Section 16.5). Then, we show that Assumption WU holds for the parameter spaces \( \Lambda_{WU} \) and \( \Lambda_{WU,P} \) for the weight matrices employed by the CQLR and CQLR\(_P\) tests, respectively, defined in Sections 5 and 15. These results combine to establish the CQLR and CQLR\(_P\) test results of Theorem 16.1. The CQLR and CQLR\(_P\) CS results of Theorem 16.1 are proved analogously to those for the tests, see the Comment to Proposition 16.3 for details.

In Section 27.6, we prove Theorem 16.1 for the AR test and CS.

27.1 Statement of Results

A general QLR\(_{WU}\) test statistic for testing \( H_0 : \theta = \theta_0 \) is defined in (16.3) as

\[ QLR_{WU,n} := AR_n - \lambda_{\min}(n \widehat{Q}_{WU,n}), \]

\[ \widehat{Q}_{WU,n} := (\hat{W}_n \hat{D}_n \hat{U}_n, \hat{\Omega}_n^{-1/2} \hat{g}_n) (\hat{W}_n \hat{D}_n \hat{U}_n, \hat{\Omega}_n^{-1/2} \hat{g}_n), \]

(27.1)

\( AR_n \) is defined in (5.2), and the dependence of \( QLR_n, \widehat{Q}_{WU,n}, \hat{W}_n, \hat{D}_n, \hat{U}_n, \hat{\Omega}_n, \) and \( \hat{g}_n \) on \( \theta_0 \) is suppressed for notational simplicity.

The general CQLR\(_{WU}\) test rejects the null hypothesis if

\[ QLR_{WU,n} > c_{k,p}(n^{1/2} \hat{W}_n \hat{D}_n \hat{U}_n, 1 - \alpha), \]

(27.2)

where \( c_{k,p}(D, 1 - \alpha) \) is defined just below (5.8).
The correct asymptotic size of the general CQLR test is established using the following theorem.

**Theorem 27.1** Suppose Assumption WU (defined in Section [16.5]) holds for some non-empty parameter space \( \Lambda_* \subset \Lambda_{WU} \). Then, the asymptotic null rejection probabilities of the nominal size \( \alpha \) CQLR\(_{WU} \) test based on \((\hat{W}_n, \hat{U}_n)\) equal \( \alpha \) under all subsequences \( \{w_n\} \) and all sequences \( \{\lambda_{w_n,h} : n \geq 1\} \) with \( \lambda_{w_n,h} \in \Lambda_* \).

**Comments:** (i) Theorem 27.1 and Proposition 16.3 imply that any nominal size \( \alpha \) CQLR test based on matrices \((\hat{W}_n, \hat{U}_n)\) that satisfy Assumption WU for some parameter space \( \Lambda_* \) has correct asymptotic size and is asymptotically similar (in a uniform sense) for the parameter space \( \Lambda_* \).

(ii) In Lemma 27.4 below, we show that the choice of matrices \((\hat{W}_n, \hat{U}_n)\) for the CQLR and CQLR\(_P\) tests (defined in Sections [3] and [15], respectively) satisfy Assumption WU for the parameter spaces \( \Lambda_{WU} \) and \( \Lambda_{WU,P} \) (defined in [16.17], respectively). In addition, Lemma 27.4 shows that \( \mathcal{F} \subset \mathcal{F}_{WU} \) and \( \mathcal{F}_P \subset \mathcal{F}_{WU} \) when \( \delta_1 \) and \( M_1 \) that appear in the definition of \( \mathcal{F}_{WU} \) are sufficiently small and large, respectively. In consequence, the CQLR and CQLR\(_P\) tests have correct asymptotic size \( \alpha \) and are asymptotically similar (in a uniform sense) for the parameter spaces \( \mathcal{F} \) and \( \mathcal{F}_P \), respectively, as stated in Theorem 16.1.

The proof of Theorem 27.1 uses Proposition 16.5 and Theorem 16.6 as well as the following lemmas.

Let \( \{D_n^c : n \geq 1\} \) be a sequence of constant (i.e., nonrandom) \( k \times p \) matrices. Here, we determine the limit as \( n \to \infty \) of \( c_{k,p}(D_n^c, 1 - \alpha) \) under certain assumptions on the singular values of \( D_n^c \).

**Lemma 27.2** Suppose \( \{D_n^c : n \geq 1\} \) is a sequence of constant (i.e., nonrandom) \( k \times p \) matrices with singular values \( \{\tau_{jn}^c : j \leq \min\{k,p\}\} \) for \( n \geq 1 \) that satisfy (i) \( \{\tau_{jn}^c \geq 0 : j \leq \min\{k,p\}\} \) are nonincreasing in \( j \) for \( n \geq 1 \), (ii) \( \tau_{jn}^c \to \infty \) for \( j \leq q \) for some \( 0 \leq q \leq \min\{k,p\} \) and (iii) Note that the set of distributions \( \mathcal{F}_{WU} \) depends on the definitions of \((W_F, U_F)\), see [16.12], and \((W_F, U_F)\) are defined differently for the QLR and QLR\(_2\) statistics, see [16.6]-[16.8] and [16.9]-[16.11], respectively. Hence, the set of distributions \( \mathcal{F}_{WU} \) differs for the CQLR and CQLR\(_2\) tests.
\(\tau_{jn}^c \to \tau_{j\infty}^c < \infty\) for \(j = q + 1, \ldots, \min\{k, p\}\). Then,

\[
c_{k,p}(D_n^c, 1 - \alpha) \to c_{k,p,q}(\tau_{\infty}^c, 1 - \alpha), \text{ where } \tau_{\infty}^c := (\tau_{(q+1)\infty}^c, \ldots, \tau_{\min\{k,p\}\infty}^c)' \in \mathbb{R}^{\min\{k,p\}-q},
\]

\[
\Upsilon(\tau_{\infty}^c) := \left( \begin{array}{c} \text{Diag}\{\tau_{i\infty}^c\} \\ 0^{(k-p)\times(p-q)} \end{array} \right) \in \mathbb{R}^{(k-q)\times(p-q)} \text{ if } k \geq p,
\]

\[
\Upsilon(\tau_{\infty}^c) := \left( \begin{array}{c} \text{Diag}\{\tau_{i\infty}^c\}, 0^{(k-q)\times(p-k)} \end{array} \right) \in \mathbb{R}^{(k-q)\times(p-q)} \text{ if } k < p,
\]

\[
c_{k,p,q}(\tau_{\infty}^c, 1 - \alpha) \text{ denotes the } 1 - \alpha \text{ quantile of } ACLR_{k,p,q}(\tau_{\infty}^c) := Z'Z - \lambda_{\min}(\Upsilon(\tau_{\infty}^c), Z_2)'(\Upsilon(\tau_{\infty}^c), Z_2), \text{ and } Z := \left( \begin{array}{c} Z_1 \\ Z_2 \end{array} \right) \sim N(0^k, I_k) \text{ for } Z_1 \in \mathbb{R}^q \text{ and } Z_2 \in \mathbb{R}^{k-q}.
\]

**Comments:** (i) The matrix \(\Upsilon(\tau_{\infty}^c)\) is the diagonal matrix containing the \(\min\{k,p\} - q\) finite limiting eigenvalues of \(D_n^c\). Note that \(\Upsilon(\tau_{\infty}^c)\) has only \(k - q\) rows, not \(k\) rows.

(ii) If \(q = p\) (which requires that \(k \geq p\)), then \(\Upsilon(\tau_{\infty}^c)\) has no columns, \(ACLR_{k,p,q}(\tau_{\infty}^c) = Z_1'Z_1 \sim \chi^2_k\), and \(c_{k,p,q}(\tau_{\infty}^c, 1 - \alpha)\) equals the \(1 - \alpha\) quantile of the \(\chi^2_k\) distribution.

(iii) If \(q \leq k\) (which requires that \(k \leq p\)), then \(\Upsilon(\tau_{\infty}^c)\) and \(Z_2\) have no rows, the \(\lambda_{\min}(\cdot)\) expression in \(ACLR_{k,p,q}(\tau_{\infty}^c)\) disappears, \(ACLR_{k,p,q}(\tau_{\infty}^c) = Z'Z \sim \chi^2_k\), and \(c_{k,p,q}(\tau_{\infty}^c, 1 - \alpha)\) is the \(1 - \alpha\) quantile of the \(\chi^2_k\) distribution.

(iv) If \(k \leq p\) and \(q < k\), then \((\Upsilon(\tau_{\infty}^c), Z_2)\) has fewer rows \((k - q)\) than columns \((p - q + 1)\) and, hence, the \(\lambda_{\min}(\cdot)\) expression in \(ACLR_{k,p,q}(\tau_{\infty}^c)\) equals zero, \(ACLR_{k,p,q}(\tau_{\infty}^c) = Z'Z \sim \chi^2_k\), and \(c_{k,p,q}(\tau_{\infty}^c, 1 - \alpha)\) is the \(1 - \alpha\) quantile of the \(\chi^2_k\) distribution.

(v) The distribution function (df) of \(ACLR_{k,p,q}(\tau_{\infty}^c)\) is shown in Lemma 27.3 below to be continuous and strictly increasing at its \(1 - \alpha\) quantile for all possible \((k, p, q, \tau_{\infty}^c)\) values, which is required in the proof of Lemma 27.2.

The following lemma proves that the df of \(ACLR_{k,p,q}(\tau_{\infty}^c)\), defined in Lemma 27.2, is continuous and strictly increasing at its \(1 - \alpha\) quantile. This is a key lemma for showing that the CQLR and CQLR_P tests have correct asymptotic size and are asymptotically similar.

**Lemma 27.3** Let \(\tau_{\infty}^c\) and \(\Upsilon(\tau_{\infty}^c)\) be defined as in Lemma 27.2. For all admissible integers \((k, p, q)\) (i.e., \(k \geq 1, p \geq 1,\) and \(0 \leq q \leq \min\{k, p\}\) and all \(\min\{k, p\} - q \geq 0\) vectors \(\tau_{\infty}^c\) with non-negative elements in non-increasing order, the df of \(ACLR_{k,p,q}(\tau_{\infty}^c) := Z'Z - \lambda_{\min}(\Upsilon(\tau_{\infty}^c), Z_2)'(\Upsilon(\tau_{\infty}^c), Z_2)\) is continuous and strictly increasing at its \(1 - \alpha\) quantile \(c_{k,p,q}(\tau_{\infty}^c, 1 - \alpha)\) for all \(\alpha \in (0, 1)\), where \(Z := (Z_1', Z_2')' \sim N(0^k, I_k)\) for \(Z_1 \in \mathbb{R}^q\) and \(Z_2 \in \mathbb{R}^{k-q}\).

The next lemma verifies Assumption WU for the choices of \((\hat{W}_n, \hat{U}_n)\) that are used to construct
the CQLR and CQLR\(_P\) tests. Part (a) of the lemma shows that \(F\) is defined for suitable choices of the constants \(\delta_1\) and \(M_1\) that appear in the definition of \(F\). Part (b) of the lemma shows that the parameter space \(F\) is defined for \((\hat{W}_n, \hat{U}_n)\) as in the CQLR test, contains \(F\) for suitable choices of the constants \(\delta_1\) and \(M_1\).

**Lemma 27.4** (a) Suppose \((\hat{W}_n, \hat{U}_n) = (\hat{\Omega}_n^{-1/2}, \hat{L}_n^{1/2})\), where \(\hat{\Omega}_n = \hat{\Omega}_n(\theta_0)\) and \(\hat{L}_n = \hat{L}_n(\theta_0)\) are defined in (1.1) and (5.7). Then, (i) Assumption WU holds for the parameter space \(\Lambda_{WU}\) with \((\hat{W}_n, \hat{U}_n) = (\hat{\Omega}_n, (\hat{R}_n, \hat{R}_n))\) for \(\hat{R}_n\) defined in (5.3), \(W_1(W_2) = W_2^{-1/2}\) for \(W_2 \in R^{k \times k}\), \(U_1(U_2) = ((\theta_0, I_p)(\Sigma^\varepsilon(\Omega_F, R_F))^{-1}(\theta_0, I_p)^{1/2}\) for \(U_2 F = (\Omega_F, R_F)\), \(h_7 = \lim W_2F_{wn} := \lim \Omega_{F_{wn}},\) and \(h_8 = \lim U_2F_{wn} := \lim (\Omega_{F_{wn}}, R_{F_{wn}}),\) where \(\Omega_F := E_F G_f g_i'\) is defined in (16.7), \(\Sigma(\Omega_F, R_F)\) is defined in (16.8), and \(\Sigma^\varepsilon(\Omega_F, R_F)\) is defined given \(\Sigma(\Omega_F, R_F)\) by (5.6), and (ii) \(F = F_{WU}\) for \(\delta_1\) sufficiently small and \(M_1\) sufficiently large in the definition of \(F_{WU}\), where \(F\) is defined in (16.1) and \(F_{WU}\) is defined in (16.12).

(b) Suppose \(g_i(\theta) = u_i(\theta)Z_i\), as in (15.1), and \((\hat{W}_n, \hat{U}_n) = (\hat{\Omega}_n^{-1/2}, \hat{L}_n^{1/2})\), where \(\hat{\Omega}_n = \hat{\Omega}_n(\theta_0)\) and \(\hat{L}_n = \hat{L}_n(\theta_0)\) are defined in (4.1) and (15.6), respectively. Then, (i) Assumption WU holds for the parameter space \(\Lambda_{WU,P}\) with \((\hat{W}_n, \hat{U}_n) = (\hat{\Omega}_n, (\hat{R}_n, \hat{R}_n))\) for \(\hat{R}_n\) defined in (15.5), \(W_1(W_2) = W_2^{-1/2}\) for \(W_2 \in R^{k \times k}\), \(U_1(U_2) = ((\theta_0, I_p)(\Sigma^\varepsilon(\Omega_F, R_F))^{-1}(\theta_0, I_p)^{1/2}\) for \(U_2 F = (\Omega_F, R_F)\), \(h_7 = \lim W_2F_{wn} := \lim \Omega_{F_{wn}},\) and \(h_8 = \lim U_2F_{wn} := \lim (\Omega_{F_{wn}}, R_{F_{wn}}),\) where \(\Omega_F := E_F G_f g_i'\) is defined in (16.11), \(\Sigma^\varepsilon(\Omega_F, R_F)\) is defined given \(\Sigma(\Omega_F, R_F)\) by (5.6), and \(R_F\) is defined in (16.10), and (ii) \(F_P \subset F_{WU}\) for \(\delta_1\) sufficiently small and \(M_1\) sufficiently large in the definition of \(F_{WU}\), where \(F_P\) is defined in (16.1) and \(F_{WU}\) is defined in (16.12).

**Comment:** Theorem 27.1, Lemma 27.4, and Proposition 16.3 combine to prove the CQLR and CQLR\(_P\) test results of Theorem 16.1, which state that the CQLR and CQLR\(_P\) tests have correct asymptotic size and are asymptotically similar (in a uniform sense) for the parameter spaces \(F\) and \(F_P\), respectively. As stated at the beginning of this section, the proofs of the CQLR and CQLR\(_P\) CS results of Theorem 16.1 are analogous to those for the tests, see the Comment to Proposition 16.3 and, hence, are not stated explicitly.

### 27.2 Proof of Theorem 27.1

Theorem 27.1 is stated in Section 27.1

For notational simplicity, the proof below is given for the sequence \(\{n\}\), rather than a subsequence \(\{w_n : n \geq 1\}\). The same proof holds for any subsequence \(\{w_n : n \geq 1\}\).
Proof of Theorem 27.1. Let

\[
Z_h = \begin{pmatrix} Z_{h1} \\ Z_{h2} \end{pmatrix} := \begin{pmatrix} h'_{3,q} g_{h_5,q}^{-1/2} g_h \\ h'_{3,k-q} g_{h_5,q}^{-1/2} g_h \end{pmatrix} = h'_{3} g_{h_5,q}^{-1/2} g_h \sim N(0^k, I_k),
\]

(27.3)

where \(Z_{h1} \in R^q\) and \(Z_{h2} \in R^{k-q}\) and the distributional result holds because \(g_h \sim N(0^k, h_5,q)\) (by (16.21)) and \(h'_{3} g_{h_5,q}^{-1/2} g_h = \lim C_n' C_n = I_k\). Note that \(Z_h\) and \((D_h, \Sigma_h)\) are independent because \(g_h\) and \((D_h, \Sigma_h)\) are independent (by Lemma 16.4(c)).

By Theorem 16.6,

\[
QLR_{WU,n} \to_d g_h h_5,q g_h - \lambda_{\min}(\Sigma_{h,p-q} g_{h_5,q}^{-1/2} g_h)^1 \Sigma_{h,k-q} h'_{3,k-q} (\Sigma_{h,p-q} g_{h_5,q}^{-1/2} g_h)^1 = Z' h Z_h - \lambda_{\min}(h'_{3,k-q} \Sigma_{h,p-q}, Z_h^2)(h'_{3,k-q} \Sigma_{h,p-q}, Z_h^2) = QLR_h,
\]

(27.4)

where the equality uses \(h'_{3} g_{h_5,q}^{-1/2} g_h = \lim C_n' C_n = I_k\). When \(p = q\), the term \(\Sigma_{h,p-q}\) does not appear and \(QLR_h := Z' h Z_h - Z' h Z_h = Z' h Z_h\).

Let \(\{\tau_{jn} : j \leq \min\{k, p\}\}\) denote the \(\min\{k, p\}\) singular values of \(n^{1/2} \widehat{W}_n D_n \widehat{U}_n\) in nonincreasing order. They equal the vector of square roots of the first \(\min\{k, p\}\) eigenvalues of \(n^{1/2} \widehat{D}_n \widehat{W}_n \widehat{D}_n \widehat{U}_n\) in nonincreasing order. Define

\[
\widehat{\tau}_n = (\widehat{\tau}_{[1]n}, \widehat{\tau}_{[2]n})' \in R^{\min\{k, p\}}, \quad \text{where}
\]

\[
\widehat{\tau}_{[1]n} = (\widehat{\tau}_{1n}, ..., \widehat{\tau}_{qn})' \in R^q \quad \text{and} \quad \widehat{\tau}_{[2]n} = (\widehat{\tau}_{(q+1)n}, ..., \widehat{\tau}_{\min\{k, p\}n})' \in R^{\min\{k, p\}-q}.
\]

(27.5)

By Proposition 16.5(a) and (b), \(\tau_{jn} \to_p \infty\) for \(j \leq q\) (or, equivalently \(\text{Diag}^{-1}\{\widehat{\tau}_{[1]n}\} \to_p 0^{q \times q}\)) and

\[
\widehat{\tau}_{[2]n} \to_d \tau_{[2]n}.
\]

(27.6)

where \(\tau_{jn} = \kappa_{jn}^{-1/2}\) for \(j \leq q\) and \(\tau_{[2]n}\) is the vector of square roots of the first \(\min\{k, p\} - q\) eigenvalues of \(\Sigma_{h,p-q} h_{3,k-q} h'_{3,k-q} \Sigma_{h,p-q} \in R^{q-p} \times (p-q)\) in nonincreasing order. (When \(q = \min\{k, p\}\), no vector \(\tau_{[2]n}\) appears.) By an almost sure representation argument, e.g., see Pollard (1990, Thm. 9.4, p. 45), there exists a probability space, say \((\Omega^0, \mathcal{F}^0, P^0)\), and random variables \((QLR^0_n, \tau^0_n, QLR^0_h, \tau^0_{[2]n})\)' defined on it such that \((QLR^0_n, \tau^0_n)'\) has the same distribution as \((QLR_{WU,n}, \tau^0_n)'\) for all \(n \geq 1\), \((QLR^0_h, \tau^0_{[2]n})'\) has the same distribution as \((QLR_h, \tau^0_{[2]n})'\), and

\[
\left(\begin{array}{c}
QLR^0_n \\
\text{Diag}^{-1}\{\tau^0_{[1]n}\} \\
\tau^0_{[2]n}
\end{array}\right) \to_d \left(\begin{array}{c}
QLR^0_h \\
0^{q \times q} \\
\tau^0_{[2]n}
\end{array}\right) \quad \text{a.s.,}
\]

(27.7)
where $\tau_{[2|h]} \in R^{\min\{k,p\} - q}$. Let

$$
\tilde{\tau}^0_n := \begin{pmatrix}
Diag\{\tau^0_n\}
\end{pmatrix} \in R^{k \times p} \quad \text{and} \quad \tilde{\tau}_n := \begin{pmatrix}
Diag\{\tau_n\}
\end{pmatrix} \in R^{k \times p} \quad \text{if} \quad k \geq p \quad \text{and} \quad (27.8)
$$

$$
\tilde{\tau}^0_n := \begin{pmatrix}
Diag\{\tau^0_n\}, 0^{k \times (p-k)}
\end{pmatrix} \in R^{k \times p} \quad \text{and} \quad \tilde{\tau}_n := \begin{pmatrix}
Diag\{\tau_n\}, 0^{k \times (p-k)}
\end{pmatrix} \in R^{k \times p} \quad \text{if} \quad k < p.
$$

The distributions of $\tilde{\tau}^0_n$ and $\tilde{\tau}_n$ are the same. The matrix $\tilde{\tau}^0_n$ has singular values given by the vector $\tau^0_n (= \tau^0_{1n}, \ldots, \tau^0_{\min\{k,p\}n})'$ whose first $q$ elements all diverge to infinity a.s. and whose last $\min\{k,p\} - q$ elements written as the subvector $\tau^0_{[2|h]}$ converge to $\tau_{[2|h]}$ a.s. Hence, for some set $C \in \mathcal{F}^0$ with $P^0(\omega \in C) = 1$, we have $\tau^0_{jn}(\omega) \rightarrow \infty$ for $j \leq q$ and $\tau^0_{[2|h]}(\omega)$, $\tau^0_{[2|h]}(\omega)$, and $\tilde{\tau}^0_n(\omega)$ denote the realizations of the random quantities $\tau^0_{jn}$, $\tau^0_{[2|h]}$, and $\tilde{\tau}^0_n$, respectively, when $\omega$ occurs. Thus, using Lemma 27.2 with $D = \tilde{\tau}^0_n(\omega)$ and $\tau_{\infty} = \tau^0_{[2|h]}(\omega)$, we have

$$
c_{k,p}(\tilde{\tau}^0_n(\omega), 1 - \alpha) \rightarrow c_{k,p}(\tau^0_{[2|h]}(\omega), 1 - \alpha) \quad \text{for all} \quad \omega \in C \quad \text{with} \quad P^0(\omega \in C) = 1, \quad (27.9)
$$

where $c_{k,p,q}(\cdot, 1 - \alpha)$ is defined in Lemma 27.2. When $q = \min\{k,p\}$, no vector $\tau_{[2|h]}(\omega)$ appears and by Comments (ii) and (iii) to Lemma 27.2 $c_{k,p,q}(\tau^0_{[2|h]}(\omega), 1 - \alpha)$ equals the $1 - \alpha$ quantile of the $\chi^2_{\min\{k,p\}}$ distribution.

Almost sure convergence implies convergence in distribution, so (27.7) and (27.9) also hold (jointly) with convergence in distribution in place of convergence a.s. These convergence in distribution results, coupled with the equality of the distributions of $(QLR^0_n, \tilde{\tau}^0_n)$ and $(QLR_{WU,n}, \tilde{\tau}_n)$ for all $n \geq 1$ and of $(QLR^0_{h}, \tau_{[2|h]}')$ and $(QLR_{h}, \tau_{[2|h]}')$, yield the following convergence result:

$$
\begin{pmatrix}
QLR_{WU,n}
\end{pmatrix}
\begin{pmatrix}
\tau_{[2|h]}' \quad \tilde{\tau}_n \quad 1 - \alpha
\end{pmatrix}
\rightarrow_d
\begin{pmatrix}
QLR_{h}
\end{pmatrix}
\begin{pmatrix}
\tau_{[2|h]}' \quad \tilde{\tau}_n \quad 1 - \alpha
\end{pmatrix}
\quad (27.10)
$$

where the first equality holds using Lemma 16.2.

Equation (27.10) and the continuous mapping theorem give

$$
P(\text{QLR}_{WU,n} > c_{k,p}(n^{1/2}\tilde{\tau}_n^0, \tilde{\tau}_n, 1 - \alpha)) \rightarrow P(\text{QLR}_{h} > c_{k,p,q}(\tau_{[2|h]}^0, 1 - \alpha)) \quad (27.11)
$$

provided $P(\text{QLR}_{h} = c_{k,p,q}(\tau_{[2|h]}^0, 1 - \alpha)) = 0$. The latter holds because $P(\text{QLR}_{h} = c_{k,p,q}(\tau_{[2|h]}^0, 1 - \alpha)|D) = 0$ a.s. In turn, the latter holds because, conditional on $D$, the df of $\text{QLR}_{h}$ is continuous at its $1 - \alpha$ quantile (by Lemma 27.3) where $\text{QLR}_{h}$ conditional on $D$ and $A\text{CLR}_{k,p,q}(\tau_{\infty}^0)$, which
appears in Lemma 27.3 have the same structure with the former being based on \( h_{3,k}^{'} \sum_{h,p} \), which is nonrandom conditional on \( \overline{D}_h \), and the latter being based on \( \Upsilon(\tau_{\infty}) \), which is nonrandom, and the former only depends on \( h_{3,k}^{'} \sum_{h,p} \) through its singular values, see (24.3) and \( c_{k,p,q}(\tau_{[2]h}, 1 - \alpha) \) is a constant (because \( \tau_{[2]h} \) is random only through \( \overline{D}_h \)).

By the same argument as in the proof of Lemma 16.2,

\[
    c_{k,p,q}(\tau_{[2]h}, 1 - \alpha) = c_{k,p,q}(h_{3,k}^{'} \sum_{h,p}, 1 - \alpha),
\]

(27.12)

where (with some abuse of notation) \( c_{k,p,q}(h_{3,k}^{'} \sum_{h,p}, 1 - \alpha) \) denotes the \( 1 - \alpha \) quantile of \( Z'Z - \lambda_{\min}(h_{3,k}^{'} \sum_{h,p} Z, Z) \\ (h_{3,k}^{'} \sum_{h,p}, Z) \) for \( Z \) as in Lemma 27.2 because \( \tau_{[2]h} \in R^{p-q} \) are the singular values of \( h_{3,k}^{'} \sum_{h,p} = R^{k-q} \times (p-q) \) and \( \Upsilon(\tau_{[2]h}) \) (which appears in ACLR_{k,p,q}(\tau_{[2]h}) = Z'Z - \lambda_{\min}(\Upsilon(\tau_{[2]h}), Z)) \) is the \( (k-q) \times (p-q) \) matrix with \( \tau_{[2]h} \) on the main diagonal and zeros elsewhere.

Thus, we have

\[
    P(QLR_h > c_{k,p,q}(\tau_{[2]h}, 1 - \alpha)) = P(QLR_h > c_{k,p,q}(h_{3,k}^{'} \sum_{h,p}, 1 - \alpha)) = EP(QLR_h > c_{k,p,q}(h_{3,k}^{'} \sum_{h,p}, 1 - \alpha)|\sum_{h,p}) = E\alpha = \alpha,
\]

(27.13)

where the second equality holds by the law of iterated expectations and the third equality holds because, conditional on \( \sum_{h,p} \), \( c_{k,p,q}(h_{3,k}^{'} \sum_{h,p}, 1 - \alpha) \) is the \( 1 - \alpha \) quantile of \( QLR_h \) (by the definitions of \( c_{k,p,q}(\cdot, 1 - \alpha) \) in Lemma 27.2 and \( QLR_h \) in (27.4)) and the df of \( QLR_h \) is continuous at its \( 1 - \alpha \) quantile (see the explanation following (27.11)). \( \square \)

### 27.3 Proof of Lemma 27.2

Lemma 27.2 is stated in Section 27.1.

The proof of Lemma 27.2 uses the following two lemmas. Let \( \{\tau_{jn}^c : j \leq \min\{k,p\}\} \) be the singular values of \( D_{jn}^c \), as in Lemma 27.2. Define

\[
\Upsilon_n^c := \begin{cases} 
\text{Diag}\{\tau_{j1}^c, \ldots, \tau_{jm}^c\} & \text{if } k \geq p \text{ and } \\
0_{(k-p)\times p} & \text{if } k < p.
\end{cases}
\]

(27.14)
Lemma 27.5 Suppose the scalar constants \( \{\tau_{jn}^c \geq 0 : j \leq \min\{k,p\}\} \) for \( n \geq 1 \) satisfy (i) \( \{\tau_{jn}^c \geq 0 : j \leq \min\{k,p\}\} \) are nonincreasing in \( j \) for \( n \geq 1 \), (ii) \( \tau_{jn}^c \to \infty \) for \( j \leq q \) for some \( 1 \leq q \leq \min\{k,p\} \), (iii) \( \tau_{jn}^c \to \tau_{j\infty}^c < \infty \) for \( j = q+1,\ldots,\min\{k,p\} \), and (iv) when \( p \geq 2 \), \( \tau_{j+1,n}^c/\tau_{jn}^c \to h_{0,j}^c \) for some \( h_{0,j}^c \in [0,1] \) for all \( j \leq \min\{k,p\} \). Let \( \Upsilon_n^c \) be defined as in (27.14). Let \( \{\kappa_{jn}^c : j \leq p+1\} \) denote the \( p+1 \) eigenvalues of \((\Upsilon_n^c, Z)(\Upsilon_n^c, Z)\), ordered to be nonincreasing in \( j \), where \( Z \sim N(0^k, I_k) \). Then,

\[
\begin{align*}
(a) & \quad \kappa_{jn}^c \to \infty \quad \forall j \leq q \quad \text{for all realizations of } Z \\
(b) & \quad \kappa_{jn}^c = o((\tau_{jn}^c)^2) \quad \forall \ell \leq q \quad \text{and} \quad \forall j = q+1,\ldots,p+1 \quad \text{for all realizations of } Z.
\end{align*}
\]

Comment: Lemma 27.5 only applies when \( q \geq 1 \), whereas Lemma 27.2 applies when \( q \geq 0 \).

Lemma 27.6 Let \( \{F_n^*(x) : n \geq 1\} \) and \( F^*(x) \) be df’s on \( R \) and let \( \alpha \in (0,1) \) be given. Suppose (i) \( F_n^*(x) \to F^*(x) \) for all continuity points \( x \) of \( F^*(x) \) and (ii) \( F^*(q_\infty + \varepsilon) > 1 - \alpha \) for all \( \varepsilon > 0 \), where \( q_\infty := \inf\{x : F^*(x) \geq 1 - \alpha\} \) is the \( 1 - \alpha \) quantile of \( F^*(x) \). Then, the \( 1 - \alpha \) quantile of \( F_n^*(x) \), viz., \( q_n := \inf\{x : F_n^*(x) \geq 1 - \alpha\} \), satisfies \( q_n \to q_\infty \).

Comment: Condition (ii) of Lemma 27.6 requires that \( F^*(x) \) is increasing at its \( 1 - \alpha \) quantile.

Proof of Lemma 27.2. By Lemma 16.2, \( c_{k,p}(D_n^c, 1 - \alpha) = c_{k,p}(\Upsilon_n^c, 1 - \alpha) \), where \( \Upsilon_n^c \) is defined in (27.14). Hence, it suffices to show that \( c_{k,p}(\Upsilon_n^c, 1 - \alpha) \to c_{k,p}(\tau_\infty^c, 1 - \alpha) \). To prove the latter, it suffices to show that for any subsequence \( \{w_n\} \) of \( \{n\} \) there exists a subsubsequence \( \{u_n\} \) such that \( c_{k,p}(\Upsilon_{u_n}, 1 - \alpha) \to c_{k,p}(\tau_\infty^c, 1 - \alpha) \). When \( p \geq 2 \), given \( \{w_n\} \), we select a subsequence \( \{u_n\} \) for which \( \tau_{(j+1)u_n}^c/\tau_{ju_n}^c \to h_{0,j}^c \) for some constant \( h_{0,j}^c \in [0,1] \) for all \( j = 1,\ldots,\min\{k,p\} - 1 \) (where \( 0/0 := 0 \)). We can select a subsequence with this property because every sequence of numbers in \([0,1]\) has a convergent subsequence by the compactness of \([0,1]\).

For notational simplicity, when \( p \geq 2 \), we prove the full sequence result that \( c_{k,p}(\Upsilon_n^c, 1 - \alpha) \to c_{k,p}(\tau_\infty^c, 1 - \alpha) \) under the assumption that

\[
\tau_{(j+1)n}^c/\tau_{jn}^c \to h_{0,j}^c \quad \text{for all } j \leq \min\{k,p\} - 1 \tag{27.15}
\]

(as well as the other assumptions on the singular values stated in the theorem).

The same argument holds with \( n \) replaced by \( u_n \) below, which is the result that is needed to complete the proof. When \( p = 1 \), we prove the full sequence result that \( c_{k,p}(\Upsilon_n^c, 1 - \alpha) \to c_{k,p}(\tau_\infty^c, 1 - \alpha) \) without the condition in (27.15) (which is meaningless in this case because there is only one value \( \tau_{ju_n}^c \), namely \( \tau_{ju_n}^c \), for each \( n \)). In this case too, the same argument holds with \( n \) replaced by \( u_n \).

\textsuperscript{67} The condition in (27.15) is required by Lemma 27.5, which is used in the proof of Lemma 27.2 below.
below, which is the result that is needed to complete the proof. We treat the cases \( p \geq 2 \) and \( p = 1 \) simultaneously from here on.

First, we show that

\[
CLR_{k,p}(\tau^c_n) := Z'Z - \lambda_{\min}((\tau^c_n, Z)'(\tau^c_n, Z)) \\
\rightarrow Z'Z - \lambda_{\min}((\tau(\tau^c_n, Z), Z)'(\tau(\tau^c_n, Z), Z)) := A\text{CLR}_{k,p,q}(\tau^c_n) \tag{27.16}
\]

for all realizations of \( Z \). If \( q = 0 \), then \(^{(27.16)}\) holds because \( \tau^c_n \rightarrow \tau(\tau^c_n) \) (by the definition of \( \tau^c_n \) in (27.14), the definition of \( \tau(\tau^c_n) \) in the statement of the Lemma 27.2 and assumption (iii) of Lemma 27.2) and the minimum eigenvalue of a matrix is a continuous function of the matrix (by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38)).

Now, we establish \(^{(27.16)}\) when \( q \geq 1 \). The (ordered) eigenvalues \( \{\kappa_{jn}^Z : j \leq p + 1\} \) of \((\tau^c_n, Z)'(\tau^c_n, Z)\) are solutions to

\[
|((\tau^c_n, Z)'(\tau^c_n, Z) - \kappa I_{p+1}| = 0 \text{ or} \\
|Q^c_n(\kappa)| = 0, \text{ where } Q^c_n(\kappa) := S^c_n(\tau^c_n, Z)'(\tau^c_n, Z)S^c_n - \kappa(S^c_n)^2 \text{ and} \\
S^c_n := \text{Diag}((\tau^c_{1n})^{-1}, \ldots, (\tau^c_{qn})^{-1}, 1, \ldots, 1) \in R^{(p+1)\times(p+1)}. \tag{27.17}
\]

Define

\[
S^c_{n,q} := \text{Diag}((\tau^c_{1n})^{-1}, \ldots, (\tau^c_{qn})^{-1}) \in R^{q\times q}. \tag{27.18}
\]

We have

\[
(\tau^c_n, Z)S^c_n = \left((\tau^c_n, Z) \begin{pmatrix} I_q \\ 0_{(p+1-q)\times q} \end{pmatrix} S^c_{n,q'}(\tau^c_n, Z) \begin{pmatrix} 0_{q\times(p+1-q)} \\ I_{p+1-q} \end{pmatrix} \right) \\
= (I_{k,q}, \tau^c_{n,p-q}, Z) \in R^{k\times(p+1)}, \text{ where} \\
I_{k,q} := \begin{pmatrix} I_q \\ 0_{(k-q)\times q} \end{pmatrix} \in R^{k\times q}, \tag{27.19}
\]

\[
\tau^c_{n,p-q} := \begin{pmatrix} 0_{q\times(p-q)} \\ \text{Diag}\{\tau^c_{(p+1)n}, \ldots, \tau^c_{pn}\} \end{pmatrix} \in R^{k\times(p-q)} \text{ if } k \geq p, \text{ and} \\
\tau^c_{n,p-q} := \begin{pmatrix} 0_{q\times(k-q)} & 0_{q\times(p-k)} \\ \text{Diag}\{\tau^c_{(p+1)n}, \ldots, \tau^c_{kn}\} & 0_{(k-q)\times(p-k)} \end{pmatrix} \in R^{k\times(p-q)} \text{ if } k < p.
\]
By (27.17) and (27.19), we have
\[
Q_n^c(\kappa) = \begin{bmatrix}
I_q & I_{k,q}'(\gamma_{n,p-q}^c, Z) \\
(\gamma_{n,p-q}^c, Z)'I_{k,q} & (\gamma_{n,p-q}^c, Z)'(\gamma_{n,p-q}^c, Z)
\end{bmatrix} - \kappa \begin{bmatrix}
(S_n^{c, q})^2 & 0^{q \times (p+1-q)} \\
0^{(p+1-q) \times q} & I_{p+1-q}
\end{bmatrix}. \tag{27.20}
\]

By the formula for the determinant of a partitioned inverse,
\[
|Q_n^c(\kappa)| = |Q_{n,1}^c(\kappa)| \cdot |Q_{n,2}^c(\kappa)|, \quad \text{where}
Q_{n,1}^c(\kappa) := I_q - \kappa(S_n^{c, q})^2 \in R^{q \times q}
\text{and}
Q_{n,2}^c(\kappa) := (\gamma_{n,p-q}^c, Z)'(\gamma_{n,p-q}^c, Z) - \kappa I_{p+1-q}
- (\gamma_{n,p-q}^c, Z)'I_{k,q}(I_q - \kappa(S_n^{c, q})^2)^{-1}I_{k,q}'(\gamma_{n,p-q}^c, Z) \in R^{(p+1-q) \times (p+1-q)}. \tag{27.21}
\]

For \( j = q + 1, \ldots, p + 1 \), we have
\[
Q_{n,1}(\kappa_{f j}^Z) = I_q - \kappa_{f j}^Z(S_n^{c, q})^2 = I_q - \text{Diag}\{\kappa_{f j}^Z(\gamma_{1n}^c)^{-2}, \ldots, \kappa_{f j}^Z(\gamma_{qn}^c)^{-2}\} = I_q + o(1) \tag{27.22}
\]
for all realizations of \( Z \), where the last equality holds by Lemma 27.5 (which applies for \( q \geq 1 \)).
This implies that \( |Q_{n,1}^c(\kappa_{f j}^Z)| \neq 0 \) for \( j = q + 1, \ldots, p + 1 \) for \( n \) large. Hence, for \( n \) large,
\[
|Q_{n,2}^c(\kappa_{f j}^Z)| = 0 \text{ for } j = q + 1, \ldots, p + 1. \tag{27.23}
\]

We write
\[
I_k = (I_{k,q}, I_{k,k-q}), \quad \text{where } I_{k,k-q} := \begin{pmatrix}
0^{q \times (k-q)} \\
I_{k-q}
\end{pmatrix} \in R^{k \times (k-q)} \tag{27.24}
\]
and \( I_{k,q} \) is defined in (27.19) \(^{68}\)

For \( j = q + 1, \ldots, p + 1 \), we have
\[
Q_{n,2}^c(\kappa_{f j}^Z) = (\gamma_{n,p-q}^c, Z)'(\gamma_{n,p-q}^c, Z) - \kappa_{f j}^Z I_{p+1-q} - (\gamma_{n,p-q}^c, Z)'I_{k,q}(I_q + o(1))I_{k,q}'(\gamma_{n,p-q}^c, Z)
= (\gamma_{n,p-q}^c, Z)'I_{k,k-q}I_{k,k-q}'(\gamma_{n,p-q}^c, Z) + o(1) - \kappa_{f j}^Z I_{p+1-q}
:= M_{n,p+1-q}^c - \kappa_{f j}^Z I_{p+1-q}, \tag{27.25}
\]
where the first equality holds by (27.22) and the definition of \( Q_{n,2}^c(\kappa) \) in (27.21) and the second equality holds because \( I_k = (I_{k,q}, I_{k,k-q})(I_{k,q}, I_{k,k-q})' = I_{k,q}I_{k,q}' + I_{k,k-q}I_{k,k-q}' \) and \( \gamma_{n,p-q}^c = O(1) \) by its definition in (27.19) and the condition (iii) of Lemma 27.2 on \( \{\gamma_{j}^c : j = q + 1, \ldots, \min\{k,p\}\} \)

\(^{68}\)There is some abuse of notation here because \( I_{k,q} \) does not equal \( I_{k,k-q} \) even if \( q \) equals \( k - q \).
for $n \geq 1$.

Equations (27.23) and (27.25) imply that $\{\kappa^Z_{jn} : j = q+1, \ldots, p+1\}$ are the $p+1-q$ eigenvalues of the matrix $M^c_{n,p+1-q}$. By the definition of $Y^c_{n,p-q}$ in (27.19) and the conditions of the lemma on $\{\tau^c_{jn} : j = q+1, \ldots, \min\{k,p\}\}$ for $n \geq 1$, we have

$$
M^c_{n,p+1-q} \rightarrow \begin{pmatrix} \left(0^{q \times (p-q)} \right), Z \\ Y^c_{n}(\tau^c_{\infty}) \end{pmatrix}' I_{k,k-q} I_{k,k-q}' \begin{pmatrix} \left(0^{q \times (p-q)} \right), Z \\ Y^c_{n}(\tau^c_{\infty}) \end{pmatrix} = (Y^c_{n}(\tau^c_{\infty}), Z_2)'(Y^c_{n}(\tau^c_{\infty}), Z_2)
$$

(27.26)

for all realizations of $Z$, where the equality uses the definitions of $Y^c_{n}(\tau^c_{\infty})$ and $Z_2$ in the statement of the lemma.

The vector of (ordered) eigenvalues of a matrix is a continuous function of the matrix (by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38)). Hence, by (27.26), the eigenvalues $\{\kappa^Z_{jn} : j = q+1, \ldots, p+1\}$ of $M^c_{n,p+1-q}$ converge (for all realizations of $Z$) to the vector of eigenvalues of $(Y^c_{n}(\tau^c_{\infty}), Z_2)'(Y^c_{n}(\tau^c_{\infty}), Z_2)$. In consequence, the smallest eigenvalue $\kappa^Z_{(p+1)n}$ (of both $M^c_{n,p+1-q}$ and $(Y^c_{n}, Z)'(Y^c_{n}, Z)$) satisfies

$$
\lambda_{\min}((Y^c_{n}, Z)'(Y^c_{n}, Z)) = \kappa^Z_{(p+1)n} \rightarrow \lambda_{\min}((Y^c_{n}(\tau^c_{\infty}), Z_2)'(Y^c_{n}(\tau^c_{\infty}), Z_2)),
$$

(27.27)

where the equality holds by the definition of $\kappa^Z_{(p+1)n}$ in (27.17). This establishes (27.16).

Now we use (27.16) to establish that $c_{k,p}(Y^c_{n}, 1-\alpha) \rightarrow c_{k,p}(\tau^c_{\infty}, 1-\alpha)$, which proves the lemma.

Let

$$
F_{k,p,q,\tau^c_{\infty}}(x) = P(ACLR_{k,p,q}(\tau^c_{\infty}) \leq x).
$$

(27.28)

By (27.16), for any $x \in R$ that is a continuity point of $F_{k,p,q,\tau^c_{\infty}}(x)$, we have

$$
1(ACLR_{k,p}(Y^c_{n}) \leq x) \rightarrow 1(ACLR_{k,p,q}(\tau^c_{\infty}) \leq x) \ a.s. \ (27.29)
$$

Equation (27.29) and the bounded convergence theorem give

$$
P(ACLR_{k,p}(Y^c_{n}) \leq x) \rightarrow P(ACLR_{k,p,q}(\tau^c_{\infty}) \leq x) = F_{k,p,q,\tau^c_{\infty}}(x).
$$

(27.30)

Now Lemma 27.6 gives the desired result, because (27.30) verifies assumption (i) of Lemma 27.6 and the df of $ACLR_{k,p,q}(\tau^c_{\infty})$ is strictly increasing at its $1-\alpha$ quantile (by Lemma 27.3), which verifies assumption (ii) of Lemma 27.6.

Proof of Lemma 27.5. The proof is similar to the proof of Lemma 17.1 given in Section 17 in
the SM of AG1. But there are enough differences that we provide a proof.

By the definition of \( q \geq 1 \) in the statement of Lemma 27.5, \( h_{6, q}^c = 0 \) if \( q < \min\{k, p\} \). If \( q = \min\{k, p\} \), then \( h_{6, q}^c \) is not defined in the statement of Lemma 27.5 and we define it here to equal zero. If \( h_{6, j}^c > 0 \), then \( \{r_{f_n}^c : n \geq 1\} \) and \( \{\tau_{j}^c(\nu) : n \geq 1\} \) are of the same order of magnitude, i.e., \( 0 < \lim_{n \to \infty} \tau_{j}^c(\nu) / r_{f_n}^c \leq 1 \). We group the first \( q \) values of \( \tau_{f_n}^c \) into groups that have the same order of magnitude within each group. Let \( G (\in \{1, \ldots, q\}) \) denote the number of groups. Note that \( G \) equals the number of values in \( \{h_{6, 1}^c, \ldots, h_{6, q}^c\} \) that equal zero. Let \( r_g \) and \( r_{g}^c \) denote the indices of the first and last values in the \( g \)th group, respectively, for \( g = 1, \ldots, G \). Thus, \( r_1 = 1 \), \( r_g = r_{g+1} - 1 \), where by definition \( r_{G+1} = q + 1 \), and \( r_{G}^c = q \). By definition, the \( \tau_{f_n}^c \) values in the \( g \)th group, which have the \( g \)th largest order of magnitude, are \( \{\tau_{r_g^c n}^c : n \geq 1\} \), \( \{\tau_{r_{g+1}^c n}^c : n \geq 1\} \). By construction, \( h_{6, j}^c > 0 \) for all \( j \in \{r_g, \ldots, r_{g+1}^c - 1\} \) for \( g = 1, \ldots, G \). (The reason is: if \( h_{6, j}^c \) is equal to zero for some \( j \leq r_{g}^c - 1 \), then \( \{\tau_{r_g^c n}^c : n \geq 1\} \) is of smaller order of magnitude than \( \{\tau_{r_{g+1}^c n}^c : n \geq 1\} \), which contradicts the definition of \( r_{g}^c \)). Also by construction, \( \lim_{n \to \infty} \tau_{f_n}^c / r_{f_n}^c = 0 \) for any \( (j, j') \) in groups \((g, g')\), respectively, with \( g < g' \).

The (ordered) eigenvalues \( \{\kappa_{f_n}^c : j \leq p + 1\} \) of \( (Y_n^c, Z)'(Y_n^c, Z) \) are solutions to the determinantal equation \( |(Y_n^c, Z)'(Y_n^c, Z) - \kappa I_{p+1}| = 0 \). Equivalently, they are solutions to

\[
|\tau_{r_{1} n}^c - 2(Y_n^c, Z)'(Y_n^c, Z) - \kappa I_{p+1}| = 0. \tag{27.31}
\]

Thus, \( \{\tau_{r_{1} n}^c - 2\kappa_{f_n}^c : j \leq p + 1\} \) solve

\[
|\tau_{r_{1} n}^c - 2(Y_n^c, Z)'(Y_n^c, Z) - \kappa I_{p+1}| = 0. \tag{27.32}
\]

Let

\[
h_{6, r_{1} n}^{c} := \text{Diag}\{1, h_{6, 1}^{c}, h_{6, 2}^{c}, \ldots, \prod_{\ell=1}^{r_{1}-1} h_{6, \ell}^{c} \} \in R^{r_{1} \times r_{1}}. \tag{27.33}
\]

When \( k \geq p \), we have

\[
\begin{bmatrix}
(\tau_{r_{1} n}^c)^{-1}(Y_n^c, Z) \\
\end{bmatrix}
= \begin{bmatrix}
h_{6, r_{1} n}^{c} + o(1) & 0^{r_{1} \times (q-r_{1}^c)} & 0^{r_{1} \times (p-q)} & O(1/\tau_{r_{1} n}^c)^{r_{1} \times 1} \\
0^{(q-r_{1}^c) \times r_{1}^c} & O(\tau_{r_{2} n}/\tau_{r_{1} n}^c)^{r_{1} \times (q-r_{1}^c)} & 0^{(q-r_{1}^c) \times (p-q)} & O(1/\tau_{r_{1} n}^c)^{(q-r_{1}^c) \times 1} \\
0^{(p-q) \times r_{1}^c} & 0^{(p-q) \times (q-r_{1}^c)} & O(1/\tau_{r_{1} n}^c)^{(p-q) \times (p-q)} & O(1/\tau_{r_{1} n}^c)^{(p-q) \times 1} \\
0^{(k-p) \times r_{1}^c} & 0^{(k-p) \times (q-r_{1}^c)} & 0^{(k-p) \times (p-q)} & O(1/\tau_{r_{1} n}^c)^{(k-p) \times 1}
\end{bmatrix}, \tag{27.34}
\]
where \( O(d_n)^{s \times s} \) denotes a diagonal \( s \times s \) matrix whose elements are \( O(d_n) \) for some scalar constants \( \{d_n : n \geq 1\} \), \( O(d_n)^{s \times 1} \) denotes an \( s \) vector whose elements are \( O(d_n) \), the equality uses \( \tau^n_{j_1}/\tau^n_{r_1} = \prod_{\ell=1}^{j-1} (\tau^n_{j_1}/\tau^n_{\ell}) = \prod_{\ell=1}^{j-1} h^n_{6, \ell} + o(1) \) for \( j = 2, \ldots, r_1^c \) (which holds by the definition of \( h^n_{6, \ell} \)) and \( \tau^n_{j_1}/\tau^n_{r_1} = O(\tau^n_{r_2}/\tau^n_{r_1}) \) for \( j = r_2, \ldots, q \) (because \( \{\tau^n_{j_1} : j \leq q\} \) are nonincreasing in \( j \)), and the convergence uses \( \tau^n_{r_1} \to \infty \) (by assumption (ii) of the lemma since \( r_1 \leq q \)) and \( \tau^n_{r_2}/\tau^n_{r_1} \to 0 \) (by the definition of \( r_2 \)).

When \( k < p \), (27.34) holds but with the rows dimensions of the submatrices in the second line changed by replacing \( p - q \) by \( k - q \) and \( k - p \) by \( p - k \) four times each.

Equation (27.34) yields

\[
(\tau^n_{r_1})^{-2}(\mathbf{Y}_n^c, Z)'(\mathbf{Y}_n^c, Z) \to \begin{bmatrix}
(h^n_{6, r_1^c})^2 & 0_{r_1^c \times (p+1-r_1^c)} \\
0_{(p+1-r_1^c) \times r_1^c} & 0_{(p+1-r_1^c) \times (p+1-r_1^c)}
\end{bmatrix}.
\tag{27.35}
\]

The vector of eigenvalues of a matrix is a continuous function of the matrix (by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38)). Hence, by (27.32) and (27.35), the first \( r_1^c \) eigenvalues of \( (\tau^n_{r_1})^{-2}(\mathbf{Y}_n^c, Z)'(\mathbf{Y}_n^c, Z) \), i.e., \( \{(\tau^n_{r_1})^{-2}\kappa^n_{j_1} : j \leq r_1^c\} \), satisfy

\[
((\tau^n_{r_1})^{-2}\kappa^n_{1_1}, \ldots, (\tau^n_{r_1})^{-2}\kappa^n_{r_1^c}) \to_p (1, h^n_{6,1}, h^n_{6,2}, \ldots, \prod_{\ell=1}^{r_1^c} h^n_{6, \ell}) \text{ and so}
\]

\[\kappa^n_{1_1} \to \infty \forall j = 1, \ldots, r_1^c\]

(27.36)

because \( \tau^n_{r_1} \to \infty \) (since \( r_1 \leq q \)) and \( h^n_{6, \ell} > 0 \) for all \( \ell \in \{1, \ldots, r_1^c - 1\} \) (as noted above). By the same argument, the last \( p + 1 - r_1^c \) eigenvalues of \( (\tau^n_{r_1})^{-2}(\mathbf{Y}_n^c, Z)'(\mathbf{Y}_n^c, Z) \), i.e., \( \{(\tau^n_{r_1})^{-2}\kappa^n_{j} : j = r_1^c + 1, \ldots, p + 1\} \), satisfy

\[
(\tau^n_{r_1})^{-2}\kappa^n_{j} \to 0 \forall j = r_1^c + 1, \ldots, p + 1.
\tag{27.37}
\]

Next, the equality in (27.34) gives

\[
(\tau^n_{r_1})^{-2}(\mathbf{Y}_n^c, Z)'(\mathbf{Y}_n^c, Z) \tag{27.38}
\]

\[
= \begin{bmatrix}
(h^n_{6, r_1^c})^2 & 0_{r_1^c \times (q-r_1^c)} & 0_{r_1^c \times (p-q)} & 0_{(1/(\tau^n_{r_1}))^{r_1^c \times 1}} \\
0_{(q-r_1^c) \times r_1^c} & O((\tau^n_{r_2}/\tau^n_{r_1})^2)_{(q-r_1^c) \times (q-r_1^c)} & 0_{(q-r_1^c) \times (p-q)} & 0_{(1/(\tau^n_{r_1}))^{(q-r_1^c) \times 1}} \\
0_{(p-q) \times r_1^c} & 0_{(p-q) \times (q-r_1^c)} & O(1/(\tau^n_{r_1})^{(p-q) \times (p-q)}) & 0_{(1/(\tau^n_{r_1}))^{(p-q) \times 1}} \\
O(1/(\tau^n_{r_1})^{r_1^c \times r_1^c}) & O((\tau^n_{r_2}/(\tau^n_{r_1}))^2)_{(r_1^c \times r_1^c)} & O(1/(\tau^n_{r_1})^{r_1^c \times (p-q)}) & O(1/(\tau^n_{r_1})^{r_1^c \times 1})
\end{bmatrix}.
\]

Equation (27.38) holds when \( k \geq p \) and \( k < p \) (because the column dimensions of the submatrices in the second line of (27.34) are the same when \( k \geq p \) and \( k < p \)).

87
Define $I_{j_1:j_2}$ to be the $(p+1) \times (j_2 - j_1)$ matrix that consists of the $j_1 + 1, ..., j_2$ columns of $I_{p+1}$ for $0 \leq j_1 < j_2 \leq p + 1$. We can write

$$I_{p+1} = (I_{0,r_1^c}, I_{r_1^c,p+1}), \quad \text{where } I_{0,r_1^c} := \begin{pmatrix} I_{r_1^c} & 0_{(p+1-r_1^c) \times r_1^c} \end{pmatrix} \in R^{(p+1) \times r_1^c} \quad \text{and}$$

$$I_{r_1^c,p+1} := \begin{pmatrix} 0_{r_1^c \times (p+1-r_1^c)} \\ I_{p+1-r_1^c} \end{pmatrix} \in R^{(p+1) \times (p+1-r_1^c)}.$$  \hspace{1cm} (27.39)

In consequence, we have

$$(\Upsilon_n^c, Z) = ((\Upsilon_n^c, Z)I_{0,r_1^c}, (\Upsilon_n^c, Z)I_{r_1^c,p+1})$$

$$\varrho_n^c := (\tau_{r_1^c I_n}^c) - 2 I_{0,r_1^c}^c (\Upsilon_n^c, Z)(\Upsilon_n^c, Z)I_{r_1^c,p+1} = o(\tau_{r_2^c I_n}^c/\tau_{r_1^c I_n}^c),$$ \hspace{1cm} (27.40)

where the last equality uses the expressions in the first row of the matrix on the rhs of (27.38) and $O(1/\tau_{r_1^c I_n}^c) = o(\tau_{r_2^c I_n}^c/\tau_{r_1^c I_n}^c)$ (because $\tau_{r_2^c I_n}^c \to \infty$).

As in (27.32), $\{ (\tau_{r_1^c I_n}^c)^{-2} \kappa_{jn}^Z : j \leq p + 1 \}$ solve

$$0 = |(\tau_{r_1^c I_n}^c)^{-2} (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z) - \kappa I_{p+1}|$$

$$= |(\tau_{r_1^c I_n}^c)^{-2} I_{0,r_1^c}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{0,r_1^c}^c - \kappa I_{r_1^c}^c|$$

$$= |(\tau_{r_1^c I_n}^c)^{-2} I_{r_1^c,p+1}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{r_1^c,p+1}^c - \kappa I_{r_1^c}^c - (\tau_{r_1^c I_n}^c)^{-2} I_{0,r_1^c}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{0,r_1^c}^c - \kappa I_{r_1^c}^c|$$

$$= |(\tau_{r_1^c I_n}^c)^{-2} I_{r_1^c,p+1}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{r_1^c,p+1}^c - \kappa I_{r_1^c}^c - (\tau_{r_1^c I_n}^c)^{-2} I_{0,r_1^c}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{0,r_1^c}^c - \kappa I_{r_1^c}^c|$$

$$\times |(\tau_{r_1^c I_n}^c)^{-2} I_{r_1^c,p+1}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{r_1^c,p+1}^c - \kappa I_{r_1^c}^c - (\tau_{r_1^c I_n}^c)^{-2} I_{0,r_1^c}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{0,r_1^c}^c - \kappa I_{r_1^c}^c|$$

$$- \varrho_n^c |(\tau_{r_1^c I_n}^c)^{-2} I_{0,r_1^c}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{0,r_1^c}^c - \kappa I_{r_1^c}^c|^{-1} \varrho_n^c|,$$ \hspace{1cm} (27.41)

where the third equality uses the standard formula for the determinant of a partitioned matrix, the definition of $\varrho_n^c$ in (27.40), and the result given in (27.42) below that the matrix which is inverted that appears in the last line of (27.41) is nonsingular for $\kappa$ equal to any solution $(\tau_{r_1^c I_n}^c)^{-2} \kappa_{jn}^Z$ to the first equality in (27.41) for $j = r_1^c + 1, ..., p + 1$.

Now we show that, for $j = r_1^c + 1, ..., p + 1$, $(\tau_{r_1^c I_n}^c)^{-2} \kappa_{jn}^Z$ cannot solve the determinantal equation $|((\tau_{r_1^c I_n}^c)^{-2} I_{0,r_1^c}^c (\Upsilon_n^c, Z)'(\Upsilon_n^c, Z)I_{0,r_1^c}^c - \kappa I_{r_1^c}^c)| = 0$ for $n$ sufficiently large, where this determinant is the first multiplicand on the rhs of (27.41). Hence, $\{ (\tau_{r_1^c I_n}^c)^{-2} \kappa_{jn}^Z : j = r_1^c + 1, ..., p + 1 \}$ must solve the determinantal equation based on the second multiplicand on the rhs of (27.41) for $n$ sufficiently
large. For \( j = r_1^c + 1, \ldots, p + 1 \), we have

\[
(r_{r_1^c n})^{-2}I_{0, r_1^c}^c (Y_{r_1^c}^c, Z)'(Y_{r_1^c}^c, Z)I_0, r_1^c - (r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z I_{r_1^c} = (h_{6, r_1^c}^c)^2 + o(1),
\]  

(27.42)

where the equality holds by \((27.35)\) and \((27.37)\). Equation \((27.42)\) and \(\lambda_{\min}(h_{6, r_1^c}^c)^2 > 0\) (which follows from the definition of \(h_{6, r_1^c}^c\) in \((27.33)\) and the fact that \(h_{6, j}^c > 0\) for all \( j \in \{1, \ldots, r_1^c - 1\} \)) establish the desired result.

For \( j = r_1^c + 1, \ldots, p + 1 \), plugging \((r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z\) into the second multiplicand on the rhs of \((27.41)\) and using \((27.40)\) and \((27.42)\) gives

\[
0 = \left| (r_{r_1^c n})^{-2}I_{r_1^c, p+1}^c (Y_{r_1^c}^c, Z)'(Y_{r_1^c}^c, Z)I_{r_1^c, r_1^c}^c + o((r_{r_1^c n}/r_{r_1^c n})^2) - (r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z I_{r_1^c, p+1} - r_1^c \right|. \tag{27.43}
\]

Thus, \(\{(r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z : j = r_1^c + 1, \ldots, p + 1\}\) solve

\[
0 = \left| (r_{r_1^c n})^{-2}I_{r_1^c, p+1}^c (Y_{r_1^c}^c, Z)'(Y_{r_1^c}^c, Z)I_{r_1^c, r_1^c}^c + o((r_{r_1^c n}/r_{r_1^c n})^2) - \kappa_{p+1} - r_1^c \right|. \tag{27.44}
\]

Or equivalently, multiplying through by \((r_{r_1^c n}/r_{r_1^c n})^{-2}\), \(\{(r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z : j = r_1^c + 1, \ldots, p + 1\}\) solve

\[
0 = \left| (r_{r_1^c n})^{-2}I_{r_1^c, p+1}^c (Y_{r_1^c}^c, Z)'(Y_{r_1^c}^c, Z)I_{r_1^c, r_1^c}^c + o(1) - \kappa_{p+1} - r_1^c \right|. \tag{27.45}
\]

by the same argument as in \((27.31)\) and \((27.32)\).

Now, we repeat the argument from \((27.32)\) to \((27.45)\) with the expression in \((27.45)\) replacing that in \((27.32)\) and with \(I_{p+1- r_1^c}, r_{r_1^c n}, r_{r_1^c n-1}^c - r_1^c, p + 1 - r_1^c, \) and \(h_{6, r_1^c}^c = \text{Diag}\{1, h_{6, r_1^c+1}^c, h_{6, r_1^c+2}^c, \ldots, \prod_{\ell = r_1^c+1} h_{6, r_1^c+1}^c\} \in R(r_1^c - r_1^c)^{r_1^c - r_1^c} \times (r_1^c - r_1^c)^{r_1^c - r_1^c}\) in place of \(I_{p+1}, r_{r_1^c n}, r_{r_1^c n-1}^c, r_1^c, p + 1 - r_1^c, \) and \(h_{6, r_1^c}^c\), respectively. In addition, \(I_{0, r_1^c}^c\) and \(I_{r_1^c, r_1^c}^c\) in \((27.41)\) are replaced by the matrices \(I_{r_1^c, r_1^c}^c\) and \(I_{r_1^c, r_1^c}^c\). This argument gives

\[
\kappa_{r_1^c n}^Z \rightarrow \infty \forall j = r_2^c, \ldots, r_2^c \text{ and } (r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z = o(1) \forall j = r_2^c + 1, \ldots, p + 1. \tag{27.46}
\]

Repeating the argument \(G - 2\) more times yields

\[
\kappa_{r_1^c n}^Z \rightarrow \infty \forall j = 1, \ldots, r_G^c \text{ and } (r_{r_1^c n})^{-2} \kappa_{r_1^c n}^Z = o(1) \forall j = r_g^c + 1, \ldots, p + 1, \forall g = 1, \ldots, G. \tag{27.47}
\]

Note that “repeating the argument \(G - 2\) more times” is justified by an induction argument that is analogous to that given in the proof of Lemma 17.1 given in Section 17 in the SM of AG1.

Because \(r_j^c = q\), the first result in \((27.47)\) proves part (a) of the lemma.
The second result in (27.47) with \( g = G \) implies: for all \( j = q + 1, \ldots, p + 1 \),

\[
(\tau_{rGn}^c)^{-2}\kappa_{jn}^Z = o(1) \tag{27.48}
\]

because \( r_{Gj}^c = q \). Either \( r_G = r_G^c = q \) or \( r_G < r_G^c = q \). In the former case, \( (\tau_{q_n}^c)^{-2}\kappa_{jn}^Z = o(1) \) for \( j = q + 1, \ldots, p + 1 \) by (27.47). In the latter case, we have

\[
\lim \frac{\tau_{q_n}^c}{\tau_{rGn}^c} = \lim \frac{\tau_{rG}^c}{\tau_{rGn}^c} = \prod_{j=r_G}^{r_G^c-1} h_{Gj}^c > 0, \tag{27.49}
\]

where the inequality holds because \( h_{Gj}^c > 0 \) for all \( j \in \{r_G, \ldots, r_G^c - 1\} \), as noted at the beginning of the proof. Hence, in this case too, \( (\tau_{q_n}^c)^{-2}\kappa_{jn}^Z = o(1) \) for \( j = q + 1, \ldots, p + 1 \) by (27.48) and (27.49). Because \( \tau_{jn}^c \geq \tau_{q_n}^c \) for all \( j \leq q \), this establishes part (b) of the lemma. \( \square \)

**Proof of Lemma 27.6.** For \( \varepsilon > 0 \) such that \( q_\infty \pm \varepsilon \) are continuity points of \( F^*(x) \), we have

\[
\begin{align*}
F_n^*(q_\infty - \varepsilon) & \to F^*(q_\infty - \varepsilon) < 1 - \alpha \text{ and } \\
F_n^*(q_\infty + \varepsilon) & \to F^*(q_\infty + \varepsilon) > 1 - \alpha
\end{align*} \tag{27.50}
\]

by assumptions (i) and (ii) of the lemma and \( F^*(q_\infty - \varepsilon) < 1 - \alpha \) by the definition of \( q_\infty \). The first line of (27.50) implies that \( q_n \geq q_\infty - \varepsilon \) for all \( n \) large. (If not, there exists an infinite subsequence \( \{w_n\} \) of \( \{n\} \) for which \( q_{w_n} < q_\infty - \varepsilon \) for all \( n \geq 1 \) and \( 1 - \alpha \leq F_{w_n}^*(q_{w_n}) \leq F_{w_n}^*(q_\infty - \varepsilon) \to F^*(q_\infty - \varepsilon) < 1 - \alpha \), which is a contradiction). The second line of (27.50) implies that \( q_n \leq q_\infty + \varepsilon \) for all \( n \) large. There exists a sequence \( \{\varepsilon_k > 0 : k \geq 1\} \) for which \( \varepsilon_k \to 0 \) and \( q_\infty \pm \varepsilon_k \) are continuity points of \( F^*(x) \) for all \( k \geq 1 \). Hence, \( q_n \to q_\infty \). \( \square \)

### 27.4 Proof of Lemma 27.3

Lemma 27.3 is stated in Section 27.1.

**Proof of Lemma 27.3.** We prove the lemma by proving it separately for four cases: (i) \( q \geq 1 \), (ii) \( k \leq p \), (iii) \( \tau_{\min(k,p)\infty}^c = 0 \), where \( \tau_{\min(k,p)\infty}^c \) denotes the \( \min \{k, p\} \)th (and, hence, last and smallest) element of \( \tau_{\infty}^c \), and (iv) \( q = 0, k > p \), and \( \tau_{p\infty}^c > 0 \). First, suppose \( q \geq 1 \). Then,

\[
ACLR_{k,p,q}(\tau_{\infty}^c) := Z'Z - \lambda_{\min}(\mathbf{Y}(\tau_{\infty}^c), Z_2)'(\mathbf{Y}(\tau_{\infty}^c), Z_2))
= Z_1'Z_1 + Z_2'Z_2 - \lambda_{\min}(\mathbf{Y}(\tau_{\infty}^c), Z_2)'(\mathbf{Y}(\tau_{\infty}^c), Z_2) \tag{27.51}
\]

and \( ACLR_{k,p,q}(\tau_{\infty}^c) \) is the convolution of a \( \chi_q^2 \) distribution (since \( Z_1'Z_1 \sim \chi_q^2 \)) and another dis-
tribution. Consider the distribution of $X + Y$, where $X$ is a random variable with an absolutely continuous distribution and $X$ and $Y$ are independent. Let $B$ be a (measurable) subset of $R$ with Lebesgue measure zero. Then,

$$P(X + Y \in B) = \int P(X + y \in B|Y = y)dP_Y(y) = \int P(X \in B - y)dP_Y(y) = 0,$$  

(27.52)

where $P_Y$ denotes the distribution of $Y$, the first equality holds by the law of iterated expectations, the second equality holds by the independence of $X$ and $Y$, and the last equality holds because $X$ is absolutely continuous and the Lebesgue measure of $B - y$ equals zero. Applying (27.52) to (27.51) with $X = Z'_1Z_1$, we conclude that $ACLR_{k,p,q}(c_\infty)$ is absolutely continuous and, hence, its df is continuous at its $1 - \alpha$ quantile for all $\alpha \in (0, 1)$.

Next, we consider the df of $X + Y$, where $X$ has support $R_+$ and $X$ and $Y$ are independent. Let $c$ denote the $1 - \alpha$ quantile of $X + Y$ for $\alpha \in (0, 1)$, and let $c_Y$ denote the $1 - \alpha$ quantile of $Y$. Since $X \geq 0$ a.s., $c_Y \leq c$. Hence, for all $\varepsilon > 0$,

$$P(Y < c + \varepsilon) \geq P(Y < c_Y + \varepsilon) \geq 1 - \alpha > 0.$$  

(27.53)

For $\varepsilon > 0$, we have

$$P(X + Y \in [c, c + \varepsilon]) = \int P(X + y \in [c, c + \varepsilon]|Y = y)dP_Y(y)$$

$$= \int P(X \in [c - y, c - y + \varepsilon])dP_Y(y) > 0,$$  

(27.54)

where the first equality holds by the law of iterated expectations, the second equality holds by the independence of $X$ and $Y$, and the inequality holds because $P(X \in [c - y, c - y + \varepsilon]) > 0$ for all $y < c + \varepsilon$ (because the support of $X$ is $R_+$) and $P(Y < c + \varepsilon) > 0$ by (27.53). Equation (27.54) implies that the df of $X + Y$ is strictly increasing at its $1 - \alpha$ quantile.

For the case when $q \geq 1$, we apply the result of the previous paragraph with $ACLR_{k,p,q}(c_\infty) = X + Y$ and $Z'_1Z_1 = X$. This implies that the df of $ACLR_{k,p,q}(c_\infty)$ is strictly increasing at its $1 - \alpha$ quantile when $q \geq 1$.

Second, suppose $k \leq p$. Then, $(\Upsilon(c_\infty), Z_2)'(\Upsilon(c_\infty), Z_2) \in R^{(p-q)(p-q+1)}$ is singular because $(\Upsilon(c_\infty), Z_2) \in R^{(k-q)(p-q+1)}$ and $k - q < p - q + 1$. Hence, $\lambda_{\min}((\Upsilon(c_\infty), Z_2)'(\Upsilon(c_\infty), Z_2)) = 0$, $ACLR_{k,p,q}(c_\infty) = Z'Z \sim \chi_{k}^2$, $ACLR_{k,p,q}(c_\infty)$ is absolutely continuous, and the df of $ACLR_{k,p,q}(c_\infty)$ is continuous and strictly increasing at its $1 - \alpha$ quantile for all $\alpha \in (0, 1)$.

Third, suppose $\tau_{\min}^{c_{\infty}} = 0$. Then, $\lambda_{\min}((\Upsilon(c_\infty), Z_2)'(\Upsilon(c_\infty), Z_2)) = 0$, $ACLR_{k,p,q}(c_\infty) = Z'Z \sim \chi_{k}^2$, $ACLR_{k,p,q}(c_\infty)$ is absolutely continuous, and the df of $ACLR_{k,p,q}(c_\infty)$ is continuous.
and strictly increasing at its $1 - \alpha$ quantile for all $\alpha \in (0, 1)$.

Fourth, suppose $q = 0$, $k > p$, and $\tau_{p, \infty}^c > 0$. In this case, $Z_2 = Z$ (because $q = 0$) and $\mathbf{Y}(\tau_{\infty}) = (D, 0_{(k-p) \times p})'$, where $D := \text{Diag}\{\tau_{\infty}^c\}$ is a pd diagonal $p \times p$ matrix (because $\tau_{p, \infty}^c > 0$). We write $Z = (Z'_a, Z'_b)' \sim N(0^k, I_k)$, where $Z_a \in R^p$ and $Z_b \in R^{k-p}$ and $Z_b$ has a positive number of elements (because $k > p$). Let $ACLR$ abbreviate $ACLR_{k,p,q}(\tau_{\infty}^c)$. In the present case, we have

$$ACLR = Z'Z - \lambda_{\text{min}} \left( \begin{pmatrix} D & Z_a \\ 0_{(k-p) \times p} & Z_b \end{pmatrix} ' \begin{pmatrix} D & Z_a \\ 0_{(k-p) \times p} & Z_b \end{pmatrix} \right)$$

$$= Z'Z - \inf_{\xi = (\xi_1, \xi_2) : \|\xi\| = 1} \left( \begin{pmatrix} \xi_1' \\ \xi_2' \end{pmatrix} \begin{pmatrix} D^2 & D Z_a \\ Z_a' D & Z_a' Z_a \end{pmatrix} \begin{pmatrix} \xi_1 \\ \xi_2 \end{pmatrix} \right) \tag{27.55}$$

$$= \sup_{\xi = (\xi_1, \xi_2) : \|\xi\| = 1} \left[ (1 - \xi_2') (Z_a' Z_a + Z_b' Z_b) - \xi_1' D^2 \xi_1 - 2 \xi_2' Z_a' D \xi_1 \right],$$

where $\xi_1 \in R^p$, $\xi_2 \in R$, and $\xi_1' \xi_1 + \xi_2^2 = 1$.

We define the following non-stochastic function

$$ACLR(z_a, \omega) := \sup_{\xi = (\xi_1, \xi_2) : \|\xi\| = 1} \left[ (1 - \xi_2') (\omega + z_a' Z_a) - \xi_1' D^2 \xi_1 - 2 \xi_2' z_a' D \xi_1 \right] \tag{27.56}$$

for $z_a \in R^p$ and $\omega \in R_+$. Note that $ACLR = ACLR(Z_a, Z_b') Z_b$.

We show below that the function $ACLR(z_a, \omega)$ is (i) nonnegative, (ii) strictly increasing in $\omega$ on $R_+ \forall z_a \neq 0^p$, and (iii) continuous in $(z_a, \omega)$ on $R^p \times R_+$, and $ACLR(z_a, \omega)$ satisfies (iv) $\lim_{\omega \to \infty} ACLR(z_a, \omega) = \infty$. In consequence, $\forall z_a \neq 0^p$, $ACLR(z_a, \omega)$ has a continuous, strictly-increasing inverse function in its second argument with domain $[ACLR(z_a, 0), \infty) \subset R_+$, which we denote by $ACLR^{-1}(z_a, x)$\footnote{Properties (i), (iii), and (iv) determine the domain of $ACLR^{-1}(z_a, x)$ for its second argument.} Using this, we have: for all $x \geq ACLR(z_a, 0)$ and $z_a \neq 0^p$, $ACLR(z_a, \omega) \leq x \iff \omega \leq ACLR^{-1}(z_a, x), \tag{27.57}$

where the condition $x \geq ACLR(z_a, 0)$ ensures that $x$ is in the domain of $ACLR^{-1}(z_a, \cdot)$.

Now, we show that for all $x_0 \in R$ and $z_a \neq 0^p$,

$$\lim_{x \to x_0} P(ACLR(z_a, Z_b') Z_b) \leq x) = P(ACLR(z_a, Z_b') Z_b) \leq x_0). \tag{27.58}$$
To prove (27.58), first consider the case \( x_0 > ACLR(z_a, 0) \) (\( \geq 0 \)) and \( z_a \neq 0^p \). In this case, we have

\[
\lim_{x \to x_0} P(ACLR(z_a, Z'_b Z_b) \leq x) = \lim_{x \to x_0} P(Z'_b Z_b \leq ACLR^{-1}(z_a, x)) = P(Z'_b Z_b \leq ACLR^{-1}(z_a, x_0)), \tag{27.59}
\]

where the first equality holds by (27.57) and the second equality holds by the continuity of the df of the \( \chi^2_{k-p} \) random variable \( Z'_b Z_b \) and the continuity of \( ACLR^{-1}(z_a, x) \) at \( x_0 \). Hence, (27.58) holds when \( x_0 > ACLR(z_a, 0) \).

Next, consider the case \( x_0 < ACLR(z_a, 0) \) and \( z_a \neq 0^p \). We have

\[
P(ACLR(z_a, Z'_b Z_b) \leq x_0) \leq P(ACLR(z_a, Z'_b Z_b) < ACLR(z_a, 0)) = 0, \tag{27.60}
\]

where the equality holds because \( ACLR(z_a, x) \) is increasing in \( x \) on \( R_+ \) by property (ii) and \( Z'_b Z_b \geq 0 \) a.s. For \( x \) sufficiently close to \( x_0 \), \( x < ACLR(z_a, 0) \) and by the same argument as in (27.60), we obtain \( P(ACLR(z_a, Z'_b Z_b) \leq x) = 0 \). Thus, (27.58) holds for \( x_0 < ACLR(z_a, 0) \).

Finally, consider the case \( x_0 = ACLR(z_a, 0) \) and \( z_a \neq 0^p \). In this case, (27.58) holds for sequences of values \( x \) that strictly decline to \( x_0 \) by the same argument as for the first case where \( x_0 > ACLR(z_a, 0) \). Next, consider a sequence that strictly increases to \( x_0 \). We have \( P(ACLR(z_a, Z'_b Z_b) \leq x) = 0 \) \( \forall x < x_0 \) by the same argument as given for the second case where \( x_0 < ACLR(z_a, 0) \). In addition, we have

\[
P(ACLR(z_a, Z'_b Z_b) \leq x_0) = P(ACLR(z_a, Z'_b Z_b) \leq ACLR(z_a, 0)) \leq P(Z'_b Z_b \leq 0) = 0, \tag{27.61}
\]

where the inequality holds because \( ACLR(z_a, x) \) is strictly increasing on for \( z_a \neq 0^p \) by property (ii). This completes the proof of (27.58).

Using (27.58), we establish the continuity of the df of \( ACLR \) on \( R \). For any \( x_0 \in R \), we have

\[
\lim_{x \to x_0} P(ACLR \leq x) = \lim_{x \to x_0} P(ACLR(Z_a, Z'_b Z_b) \leq x) = \lim_{x \to x_0} \int P(ACLR(z_a, Z'_b Z_b) \leq x) dF_{z_a}(z_a)
\]

\[
= \int P(ACLR(z_a, Z'_b Z_b) \leq x_0) dF_{z_a}(z_a)
\]

\[
= P(ACLR \leq x_0), \tag{27.62}
\]

where \( F_{z_a}(\cdot) \) denotes the df of \( Z_a \), the first and last equalities hold because \( ACLR = ACLR(Z_a, Z'_b Z_b) \), the second equality uses the independence of \( Z_a \) and \( Z_b \), and the third equality holds by the
bounded convergence theorem using (27.58) and \( P(Z_a \neq 0^p) = 1 \). Equation (27.62) shows that the
df of ACLR is continuous on \( R \).

Next, we show that the df of ACLR is strictly increasing at all \( x > 0 \). Because the df of ACLR
is continuous on \( R \) and equals 0 for \( x \leq 0 \) (because ACLR \( \geq 0 \) by property (i)), the \( 1 - \alpha \) quantile
of ACLR is positive. Hence, the former property implies that the df of ACLR is strictly increasing
at its \( 1 - \alpha \) quantile, as stated in the Lemma.

For \( x \geq ACLR(z_a, 0), \delta > 0, \text{and } z_a \neq 0^p \), we have

\[
P(ACLR(z_a, Z_b^\prime Z_b) \in [x, x + \delta]) = P \left( Z_b^\prime Z_b \in [ACLR^{-1}(z_a, x), ACLR^{-1}(z_a, x + \delta)] \right) > 0, \tag{27.63}
\]

where the equality holds by (27.57) and the inequality holds because \( ACLR^{-1}(z_a, x) \) is strictly
increasing in \( x \) for \( x \in [ACLR(z_a, 0), \infty) \) when \( z_a \neq 0^p \) and \( Z_b^\prime Z_b \) has a \( \chi_k^2 \) distribution, which is absolutely continuous.

The function \( ACLR(z_a, 0) \) is continuous at all \( z_a \in R^p \) (by property (iii)) and \( ACLR(0^p, 0) = 0 \)
(by a simple calculation using (27.56)). In consequence, for any \( x > 0 \), there exists a vector \( z_a^* \in R^p \)
and a constant \( \varepsilon > 0 \) such that \( ACLR(z_a, 0) < x \) for all \( z_a \in B(z_a^*, \varepsilon) \), where \( B(z_a^*, \varepsilon) \) denotes a
ball centered at \( z_a^* \) with radius \( \varepsilon > 0 \). Using this, we have: for any \( x > 0 \) and \( \delta > 0 \),

\[
P(ACLR \in [x, x + \delta]) = \int_{B(z_a^*, \varepsilon)} P(ACLR(z_a, Z_b^\prime Z_b) \in [x, x + \delta]) dF_{Z_a}(z_a)
\geq \int_{B(z_a^*, \varepsilon)} P(ACLR(z_a, Z_b^\prime Z_b) \in [x, x + \delta]) dF_{Z_a}(z_a) > 0, \tag{27.64}
\]

where the equality uses the independence of \( Z_a \) and \( Z_b \), the first inequality holds because \( B(z_a^*, \varepsilon) \subset R \) and the integrand is nonnegative, and the second inequality holds because \( P(Z_a \in B(z_a^*, \varepsilon)) > 0 \)
(since \( Z_a \sim N(0^p, I_p) \) and \( B(z_a^*, \varepsilon) \) is a ball with positive radius) and the integrand is positive for
\( z_a \in B(z_a^*, \varepsilon) \) by (27.63) using the fact that \( x > ACLR(z_a, 0) \) for all \( z_a \in B(z_a^*, \varepsilon) \) by the definition
of \( B(z_a^*, \varepsilon) \). Equation (27.64) shows that the df of ACLR is strictly increasing at all \( x > 0 \) and,
hence, at its \( 1 - \alpha \) quantile which is positive.

It remains to verify properties (i)-(iv) of the function \( ACLR(z_a, \omega) \), which are stated above.
The function \( ACLR(z_a, \omega) \) is seen to be nonnegative by replacing the supremum in (27.56) by
\( \xi = (0^p, 1)' \). Hence, property (i) holds. The function \( ACLR(z_a, \omega) \) can be written as

\[
ACLR(z_a, \omega) = \omega + z_a^\prime z_a - \lambda_{\min} \begin{pmatrix} D^2 & Dz_a \\ z_a' D & z_a' z_a + \omega \end{pmatrix} \tag{27.65}
\]

by analogous calculations to those in (27.55). The minimum eigenvalue is a continuous function
of a matrix is a continuous function of its elements by Elsner’s Theorem, see Stewart (2001, Thm. 3.1, pp. 37–38). Hence, ACLR(z_a, ω) is continuous in (z_a, ω) ∈ R^p × R_+ and property (iii) holds.

For any ρ^2 ∈ [0,1) and ρ ∈ R^p such that ρ_i ρ_1 = 1 - ρ^2, we have

\[ ACLR(z_a, ω) \geq (1 - ρ^2)(ω + z'_a z_a) - ρ_1 D^2 ρ_1 - 2ρ_2 z'_a D ρ_1 \to \infty \text{ as } ω \to \infty, \tag{27.66} \]

where the inequality holds by replacing the supremum over ρ in (27.56) by the same expression evaluated at ρ = (ρ_1, ρ_2)', and the divergence to infinity uses 1 - ρ^2 > 0. Hence, property (iv) holds.

It remains to verify property (ii), which states that ACLR(z_a, ω) is strictly increasing in ω on \( R_+ \forall z_a \neq 0^p \). For ω ∈ R_+, let \( ρ_ω = (ρ_ω,1, ρ_ω,2)' \) (for \( ρ_ω,1 \in R^p \) and \( ρ_ω,2 \in R \)) be such that \( ||ρ_ω|| = 1 \) and

\[ ACLR(z_a, ω) = (1 - ρ^2_ω)(ω + z'_a z_a) - ρ_ω,1 D^2 ρ_ω,1 - 2ρ_ω,2 z'_a D ρ_ω,1. \tag{27.67} \]

Such a vector \( ρ_ω \) exists because the supremum in (27.56) is the supremum of a continuous function over a compact set and, hence, the supremum is attained at some vector \( ρ_ω \). (Note that \( ρ_ω \) typically depends on \( z_a \) as well as \( ω \).) Using (27.67), we obtain: for all \( δ > 0 \), if \( ρ^2_ω < 1 \),

\[ ACLR(z_a, ω) < (1 - ρ^2_ω)(ω + δ + z'_a z_a) - ρ_ω,1 D^2 ρ_ω,1 - 2ρ_ω,2 z'_a D ρ_ω,1 \]

\[ \leq \sup_{ρ = (ρ_1, ρ_2)'} \left[ (1 - ρ^2_ω)(ω + δ + z'_a z_a) - ρ_1 D^2 ρ_1 - 2ρ_2 z'_a D ρ_1 \right] \]

\[ = ACLR(z_a, ω + δ). \tag{27.68} \]

Equation (27.68) shows that ACLR(z_a, ω) is strictly increasing at ω provided \( ρ^2_ω < 1 \).

Next, we show that \( ρ^2_ω = 1 \) only if \( z_a = 0^p \). By (27.56) and (27.67), \( ρ_ω \) maximizes the rhs expression in (27.56) over \( ρ \in R^{p+1} \) subject to \( ρ_1 + ρ_2 = 1 \). The Lagrangian for the optimization problem is

\[ (1 - ρ^2_ω)(ω + z'_a z_a) - ρ_1 D^2 ρ_1 - 2ρ_2 z'_a D ρ_1 + γ(1 - ρ^2_ω - ρ_1), \tag{27.69} \]

where \( γ \in R \) is the Lagrange multiplier. The first-order conditions of the Lagrangian with respect to \( ρ_1 \), evaluated at the solution \( (ρ_1, ω, ρ_2)' \) and the corresponding Lagrange multiplier, say \( γ_ω \), are

\[ -2D^2 ρ_ω,1 - 2ρ_ω,2 D z_a - 2γ_ω ρ_ω = 0^p. \tag{27.70} \]

The solution is \( ρ_ω,1 = 0^p \) (which is an interior point of the set \( \{ ρ_1 : ||ρ_1|| \leq 1 \} \)) only if \( ρ_ω,2 = 0 \) or \( z_a = 0^p \) (because \( D \) is a pd diagonal matrix). Thus, \( ρ^2_ω = 1 - ρ_ω,1 ρ_ω,1 = 1 \) only if \( z_a = 0^p \). This concludes the proof of property (iv). □
27.5 Proof of Lemma 27.4

Lemma 27.4 is stated in Section 27.1.

For notational simplicity, the following proof is for the sequence \(\{n\}\), rather than a subsequence \(\{w_n : n \geq 1\}\). The same proof holds for any subsequence \(\{w_n : n \geq 1\}\).

**Proof of Lemma 27.4.** We prove part (a)(i) first. We have

\[
\hat{W}_{2n} = n^{-1} \sum_{i=1}^{n} (g_i g_i' - E_{F_n} g_i g_i') - \hat{g}_n \hat{g}_n' + E_{F_n} g_i g_i' \rightarrow_p h_{5,g},
\]

where the convergence holds by the WLLN (using the moment conditions in \(\mathcal{F}\)), \(E_{F_n} g_i = 0^k\), and \(\lambda_{7,F_n} = W_{2F_n} = \Omega_{F_n} := E_{F_n} g_i g_i' \rightarrow h_{5,g}\) (by the definition of the sequence \(\{\lambda_{n,h} : n \geq 1\}\)). Hence, Assumption WU(a) holds for the parameter space \(\Lambda_{WU}\) with \(h_7 = h_{5,g}\).

Next, we establish Assumption WU(b) for the parameter space \(\Lambda_{WU}\). Using the definition of \(\hat{V}_n (= \hat{v}_n(\theta_0))\) in (5.3), we have

\[
\hat{V}_n = n^{-1} \sum_{i=1}^{n} f_i f_i' - \hat{f}_n \hat{f}_n' = E_{F_n} f_i f_i' - (E_{F_n} f_i)(E_{F_n} f_i)' + o_p(1)
\]

by the WLLN’s (using the moment conditions in \(\mathcal{F}\)). In consequence, we have

\[
\hat{R}_n = (B' \otimes I_k) \left( E_{F_n} f_i f_i' - (E_{F_n} f_i)(E_{F_n} f_i)' \right) (B \otimes I_k) + o_p(1)
\]

\[
\rightarrow_p R_h := (B' \otimes I_k) \left[ h_5 - vec((0^k, h_4)) vec((0^k, h_4))' \right] (B \otimes I_k),
\]

where \(B = B(\theta_0)\) is defined in (5.3), the convergence uses the definitions of \(\lambda_{4,F}\) and \(\lambda_{5,F}\) in (16.16), and the definition of \(\{\lambda_{n,h} : n \geq 1\}\) in (16.18).

This yields

\[
\widehat{U}_{2n} = (\hat{\Omega}_n, \hat{R}_n) \rightarrow_p (h_{5,g}, R_h) = h_8,
\]

which verifies Assumption WU(b) for the parameter space \(\Lambda_{WU}\) for part (a) of the lemma.

Now we establish Assumption WU(c) for the parameter space \(\Lambda_{WU}\) for part (a) of the lemma. We take \(\mathcal{W}_2\) (which appears in the statement of Assumption WU(c)) to be the space of psd \(k \times k\) matrices and \(\mathcal{U}_2\) (which also appears in Assumption WU(c)) to be the space of non-zero psd matrices \((\Omega, R)\) for \(\Omega \in R^{k \times k}\) and \(R \in R^{(p+1)k \times (p+1)k}\). By the definition of \(\hat{W}_{2n}\), \(\hat{W}_{2n} \in \mathcal{W}_2\) a.s. We have \(W_{2F} \in \mathcal{W}_2\ \forall F \in \mathcal{F}_{WU}\) because \(W_{2F} = E_{F} g_i g_i'\) is psd. We have \(U_{2F} \in \mathcal{U}_2\ \forall F \in \mathcal{F}_{WU}\) because \(U_{2F} = (\Omega_F, R_F), \Omega_F := E_{F} g_i g_i'\) is psd and non-zero (by the last condition in \(\mathcal{F}\), even if that condition is weaken to \(\lambda_{\text{max}}(E_{F} g_i g_i') \geq \delta\) and \(R_F := (B' \otimes I_k) V_F (B \otimes I_k)\) is psd and non-zero.

96
because \( B \) is nonsingular and \( V_F \) (defined in (16.7)) is non-zero by the argument given in the paragraph containing (27.77) below. By their definitions, \( \breve{\Omega}_n \) and \( \breve{R}_n \) are psd. In addition, they are non-zero wp→1 by (27.74) and the result just established that the two matrices that comprise \( h_8 \) are non-zero. Hence, \((\breve{\Omega}_n, \breve{R}_n) \in \mathcal{U}_2 \) wp→1.

The function \( W_1(W_2) = W_2^{-1/2} \) is continuous at \( W_2 = h_7 \) on \( \mathcal{W}_2 \) because \( \lambda_{\text{min}}(h_7) > 0 \) (given that \( h_7 = \lim E_{F_n} g_i g_i' \) and \( \lambda_{\text{min}}(E_F g_i g_i') \geq \delta \) by the last condition in \( F \)).

The function \( U_1(\cdot) \) defined in (16.8) is well-defined in a neighborhood of \( h_8 \) and continuous at \( h_8 \) provided all psd matrices \( \Omega \in R^{k \times k} \) and \( R \in R^{(p+1)k \times (p+1)k} \) with \((\Omega, R)\) in a neighborhood of \( h_8 := \lim(\Omega_{F_n}, R_{F_n}) \) are such that \( \Sigma^e(\Omega, R) \) is nonsingular, where \( \Sigma(\Omega, R) \) is defined in the paragraph containing (16.8) with \((\Omega, R)\) in place of \((\Omega_F, R_F)\) and \( \Sigma^e(\Omega, R) \) is defined given \( \Sigma(\Omega, R) \) by (5.6). Lemma 22.1(b) shows that \( \Sigma^e(\Omega, R) \) is nonsingular provided \( \lambda_{\text{max}}(\Sigma(\Omega, R)) > 0 \). We have

\[
\lambda_{\text{max}}(\Sigma(\Omega, R)) \geq \max_{j \leq p+1} \Sigma_{jj}(\Omega, R) = \max_{j \leq p+1} \text{tr}(\Omega^{-1/2} R_{jj} \Omega^{-1/2}) / k \\
\geq \max_{j \leq p+1} \lambda_{\text{max}}(\Omega^{-1/2} R_{jj} \Omega^{-1/2}) / k = \max_{j \leq p+1} \sup_{\lambda ||\lambda|| = 1} \lambda^{1/2} \Omega^{-1/2} R_{jj} \Omega^{-1/2} \lambda \cdot ||\Omega^{-1/2}\lambda||^2 / k \\
\geq \max_{j \leq p+1} \lambda_{\text{max}}(R_{jj}) \lambda_{\text{min}}(\Omega^{-1}) / k > 0,
\]

(27.75)

where \( \Sigma_{jj}(\Omega, R) \) denotes the \((j, j)\) element of \( \Sigma(\Omega, R) \), \( R_{jj} \) denotes the \((j, j)\) \( k \times k \) submatrix of \( R \), the first inequality holds by the definition of \( \lambda_{\text{max}}(\cdot) \), the first equality holds by (5.5) with \((\Omega, R)\) in place of \((\breve{\Omega}_n(\theta), \breve{R}_n(\theta))\), the second inequality holds because the trace of a psd matrix equals the sum of its eigenvalues by a spectral decomposition, the third inequality holds by the definition of \( \lambda_{\text{min}}(\cdot) \), and the last inequality holds because the conditions in \( F \) imply that \( \lambda_{\text{min}}(\Omega^{-1}) = 1 / \lambda_{\text{max}}(\Omega) > 0 \) for \( \Omega \) in some neighborhood of \( \lim \Omega_{F_n} \) (because \( \lambda_{\text{max}}(\Omega_F) = \sup_{\lambda \in R^k: ||\lambda|| = 1} E_F(\lambda g_i)^2 \leq E_F ||g_i||^2 \leq M_2/(2+\gamma) < \infty \) for all \( F \in \mathcal{F} \) using the Cauchy-Bunyakovsky-Schwarz inequality) and \( \inf_{F \in \mathcal{F}} \lambda_{\text{max}}(R_F) > 0 \), which we show below, implies that \( \lambda_{\text{max}}(R_{jj}) > 0 \) for some \( j \leq p + 1 \).

To establish Assumption WU(c) for part (a) of the lemma, it remains to show that

\[
\inf_{F \in \mathcal{F}} \lambda_{\text{max}}(R_F) > 0.
\]

(27.76)

We show that the last condition in \( \mathcal{F} \), i.e., \( \inf_{F \in \mathcal{F}} \lambda_{\text{min}}(E_F g_i g_i') > 0 \) implies (27.76). In fact, the last condition in \( \mathcal{F} \) is very much stronger than is needed to get (27.76). (The full strength of the last condition in \( \mathcal{F} \) is used in the proof of Lemma 16.4, see Section 25, because \( \hat{\Omega}_n^{-1/2} \) enters the definition of \( \hat{D}_n \) and \( \hat{\Omega}_n - \Omega_{F_n} \rightarrow_p 0^{k \times k} \), where \( \Omega_F = E_F g_i g_i' \).) We show that (27.76) holds provided \( \inf_{F \in \mathcal{F}} \lambda_{\text{max}}(E_F g_i g_i') > 0 \).
Let $x^* \in R^{(p+1)k}$ be such that $\|x^*\| = 1$ and $\lambda_{\text{max}}(V_F) = x^* V_F x^*$. Let $x^* = (B \otimes I_k)^{-1}x^*$. Then, we have
\[
\lambda_{\text{max}}(R_F) := \lambda_{\text{max}}((B' \otimes I_k) V_F (B \otimes I_k)) = \sup_{x \in R^{(p+1)k}, \|x\| = 1} x'(B' \otimes I_k) V_F (B \otimes I_k) x
\]
\[
\geq x''(B' \otimes I_k) V_F (B \otimes I_k) x^* \cdot \|x\|^{-2} = x'' V_F x^*/(x''(B \otimes I_k)^{-1} x^*)
\]
\[
\geq \lambda_{\text{max}}(V_F)/\lambda_{\text{max}}((B \otimes I_k)^{-1} (B \otimes I_k)^{-1}) = K \lambda_{\text{max}}(V_F),
\]
where $K := 1/\lambda_{\text{max}}((B \otimes I_k)^{-1} (B \otimes I_k)^{-1})$ is positive and does not depend on $F$ (because $B$ and $B \otimes I_k$ are nonsingular and do not depend on $F$ for $B = B(\theta_0)$ defined in (5.3)). Next, \(\inf_{F \in \mathcal{F}} \lambda_{\text{max}}(V_F) \geq \inf_{F \in \mathcal{F}} \lambda_{\text{max}}(E_F g_i g'_i) \geq \delta\) because $E_F g_i g'_i$ is the upper left $p \times p$ submatrix of $V_F$, which implies that $\lambda_{\text{max}}(V_F) \geq \lambda_{\text{max}}(E_F g_i g'_i)$, and $\lambda_{\text{max}}(E_F g_i g'_i) \geq \delta$ by the last condition in $\mathcal{F}$. This completes the verification (27.76) and the verification of Assumption WU(c) in part (a) of the lemma.

Now we prove part (a)(ii). It suffices to show that $\mathcal{F} \subset \mathcal{F}_{WU}$ for $\delta_1$ sufficiently small and $M_1$ sufficiently large because $\mathcal{F}_{WU} \subset \mathcal{F}$ by the definition of $\mathcal{F}_{WU}$. We need to show that the four conditions in the definition of $\mathcal{F}_{WU}$ in (16.12) hold.

(I) We show that $\inf_{F \in \mathcal{F}} \lambda_{\text{min}}(W_F) > 0$, where $W_F := W_1(W_{2F}) := \Omega_{F}^{-1/2} := (E_F g_i g'_i)^{-1/2}$ (by (16.5), (16.8), and (16.11)). The inequality $E_F \|g_i\|^{2+\gamma} \leq M$ in $\mathcal{F}$ implies $\lambda_{\text{min}}(W_F) \geq \delta_1$ for $\delta_1$ sufficiently small (because the latter holds if $\lambda_{\text{max}}(W_F^{-2}) \leq \delta_1^{-2}$ and $W_F^{-2} = \Omega_{F}^{-1/2} = (E_F g_i g'_i)$.

(II) We show that $\sup_{F \in \mathcal{F}} \|W_F\| < \infty$, where $W_F := W_1(W_{2F}) := \Omega_{F}^{-1/2} := (E_F g_i g'_i)^{-1/2}$ (by (16.5) and (16.8)). We have $\inf_{F \in \mathcal{F}} \lambda_{\text{min}}(\Omega_{F}) > 0$ (by the last condition in $\mathcal{F}$).

(III) We show that $\inf_{F \in \mathcal{F}} \lambda_{\text{min}}(U_F) > 0$, where in the present case $U_F := U_1(U_{2F}) := ((\theta_0, I_p)(\Sigma_{F}^e)^{-1}(\theta_0, I_p)'^{1/2}$ and $\Sigma_{F} := \Sigma(\Omega_{F}, R_F)$ has $(j, \ell)$ element equal to $\text{tr}(R_{jF}^{\ell F} \Omega_{F}^{-1})/k$ (by (16.8)). We have $\sup_{F \in \mathcal{F}} \|R_F\| = \sup_{F \in \mathcal{F}} \|(B' \otimes I_k) \text{Var}_F(f_i) (B \otimes I_k)\| < \infty$ (where the inequality uses the condition $E_F \|g_i^j, \text{vec}(G_l^\ell)\|^{2+\gamma} \leq M$ in $\mathcal{F}$). In addition, $\inf_{F \in \mathcal{F}} \lambda_{\text{min}}(\Omega_{F}) > 0$ (by the last condition in $\mathcal{F}$). The latter results imply that $\sup_{F \in \mathcal{F}} \|\Sigma_F\| < \infty$ (because $\Sigma_{F}$ minimizes $\|(I_{p+1} \otimes \Omega_{F}^{-1/2}) \Sigma \otimes \Omega_{F} - R_F\| (I_{p+1} \otimes \Omega_{F}^{-1/2})\|$, see the paragraph containing (16.8)). This implies that $\sup_{F \in \mathcal{F}} \|\Sigma_{F}\| < \infty$. In addition, $\Sigma_{F}$ is nonsingular $\forall F \in \mathcal{F}$ (because $\inf_{F \in \mathcal{F}} \lambda_{\text{min}}(\Sigma_{F}) > 0$ by the proof of result (IV) below). The last two results imply the desired result $\inf_{F \in \mathcal{F}} \lambda_{\text{min}}(U_F) = \inf_{F \in \mathcal{F}} \lambda_{\text{min}}((\theta_0, I_p)(\Sigma_{F}^e)^{-1}(\theta_0, I_p)'^{1/2}) > 0$ (because $A := (\theta_0, I_p) \in R^p \times (p+1)$ has full row rank $p$ and $\lambda_{\text{min}}(A) = \inf_{\lambda \in R^p, \|\lambda\| = 1} \|A(\Sigma_{F}^e)^{-1} A'\lambda\| \geq \inf_{\lambda \in R^p, \|\lambda\| = 1} \|A^\ell \|^{2} = \lambda_{\text{min}}((\Sigma_{F}^e)^{-1}) \lambda_{\text{min}}(AA') \geq \delta_2$ for some $\delta_2 > 0$ that does not depend on $F$).

(IV) We show that $\sup_{F \in \mathcal{F}} \|U_F\| < \infty$, where $U_F$ is defined in (III) immediately above. By the
same calculations as in (27.75) (which use (27.76)) with \( \Sigma_F \) and \( (\Omega_F, R_F) \) in place of \( \Sigma(\Omega, R) \) and \( (\Omega, R) \), respectively, we have \( \inf_{F \in \mathcal{F}_p} \lambda_{\text{max}}(\Sigma_F) > 0 \). The latter implies \( \inf_{F \in \mathcal{F}_p} \lambda_{\text{min}}(\Sigma_F^T) > 0 \) by Lemma 22.1(b). In turn, the latter implies the desired result \( \sup_{F \in \mathcal{F}_p} \|U_F\| = \sup_{F \in \mathcal{F}_p} \|((\theta_0, I_p) \times (\Sigma_F^T)^{-1}(\theta_0, I_p))^{1/2}\| < \infty \).

This completes the proof of part (a)(ii).

Now, we prove part (b)(i) of the lemma. Assumption WU(a) holds for the parameter space \( \Lambda_{WU,P} \) with \( h_\theta = h_{5,g} \) by the same argument as for part (a)(i).

Next, we verify Assumption WU(b) for the parameter space \( \Lambda_{WU,P} \) for \( \hat{U}_{2n} = (\hat{\Omega}_n, \hat{R}_n) \). Using the definition of \( \hat{V}_n = (\hat{\nu}_n(\theta_0)) \) in (15.5), we have

\[
\hat{V}_n = n^{-1} \sum_{i=1}^n (u_i' u_i'' \otimes Z_i Z_i') - n^{-1} \sum_{i=1}^n (\hat{a}_{in} \hat{u}_i'' \otimes Z_i Z_i') - n^{-1} \sum_{i=1}^n (u_i' \hat{a}_{in} \otimes Z_i Z_i').
\]

Using Lemma 22.1(b), in turn, the latter implies the desired result.

We have

\[
n^{-1} \sum_{i=1}^n (u_i' u_i'' \otimes Z_i Z_i') = E_{F_n} f_i f'_i + o_p(1),
\]

\[
\hat{\Xi}_n = (n^{-1} Z_i Z_i')^{-1} n^{-1} Z_i \hat{u}_i'' = (E_{F_n} Z_i Z_i')^{-1} E_{F_n} Z_i u_i'' + o_p(1)
\]

\[
= (E_{F_n} Z_i Z_i')^{-1} E_{F_n} (g_i, G_i) + o_p(1) =: \Xi_{F_n} + o_p(1),
\]

\[
n^{-1} \sum_{i=1}^n (\hat{a}_{in} \hat{u}_i'' \otimes Z_i Z_i') = n^{-1} \sum_{i=1}^n (\hat{\Xi}_n Z_i u_i'' \otimes Z_i Z_i') = E_{F_n}(\Xi_{F_n} (g_i, G_i) \otimes Z_i Z_i') + o_p(1), \quad \text{and}
\]

\[
n^{-1} \sum_{i=1}^n (a_{in} a''_i \otimes Z_i Z_i') = n^{-1} \sum_{i=1}^n (\hat{\Xi}_n Z_i Z_i' \Xi_{F_n} \otimes Z_i Z_i') = E_{F_n}(\Xi_{F_n} Z_i Z_i' \Xi_{F_n} \otimes Z_i Z_i') + o_p(1),
\]

where the first line holds by the WLLN’s (since \( u_i' u_i'' \otimes Z_i Z_i' = f_i f'_i \) for \( f_i \) defined in (16.10) and using the moment conditions in \( \mathcal{F} \)), the second line holds by the WLLN’s (using the conditions in \( \mathcal{F} \) and \( \mathcal{F}_P \)), Slutsky’s Theorem, and \( Z_i u_i'' = (g_i, G_i) \), the fourth line holds by the WLLN’s (using \( E_F(\|\|g_i, G_i\|\| \cdot \|Z_i\|^2)^{1/4} \leq (E_F(\|g_i, G_i\|^2)^{1/2}E_F\|Z_i\|^4)^{1/4} < \infty \) for \( \gamma > 0 \) by the Cauchy-Bunyakovsky-Schwarz inequality and the moment conditions in \( \mathcal{F} \) and \( \mathcal{F}_P \)) and the result of the second and third lines, and the fifth line holds by the WLLN’s (using the moment conditions in \( \mathcal{F} \) and \( \mathcal{F}_P \)) and the result of the second and third lines.

Equations (16.10) (which defines \( \hat{\nu}_F \)) with \( F = F_n \), (27.78), and (27.79) combine to give

\[
\hat{V}_n - \hat{\nu}_F_n \to_p 0.
\]
Using the definitions of $\tilde{R}_n$ and $\tilde{R}_F$ (in (15.5) and (16.10), (27.71), (27.80), and $h_T := \lim W_{2F_n} = \lim \Omega_{F_n}$ yield

$$\left(\Omega_n, \tilde{R}_n\right) \to_p \lim(\Omega_{F_n}, \tilde{R}_F_n) =: h_8. \quad (27.81)$$

This establishes Assumption WU(b) for the parameter space $\Lambda_{WU,F}$ for part (b) of the lemma.

Assumption WU(c) holds for the parameter space $\Lambda_{WU,F}$, with $W_2$ and $U_2$ defined as above, by the argument given above to verify Assumption WU(c) in part (a) of the lemma plus the inequality $\inf_{F \in F} \lambda_{\max}(\tilde{R}_F) > 0$. The latter holds by the same argument as used above to show $\inf_{F \in F} \lambda_{\max}(R_F) > 0$ (which is given in the paragraph containing (27.77) and the paragraph following it), but with (i) $\tilde{R}_F$ in place of $R_F$ and (ii) $\inf_{F \in F} \lambda_{\max}(\tilde{V}_F) > 0$, rather than $\inf_{F \in F} \lambda_{\max}(V_F) > 0$, holding. Condition (ii) holds because $\inf_{F \in F} \lambda_{\max}(\tilde{V}_F) \geq \inf_{F \in F} \lambda_{\max}(E_Fg_lg_i') > 0$ because $\tilde{V}_F$ can be written as $E_F(u^*_i - \Xi'_FZ_i)(u^*_i - \Xi'_FZ_i)' \otimes Z_iZ_i'$, the first element of $\Xi'_FZ_i$ is zero (because $\Xi_F := (E_FZ_iZ_i')^{-1}E_F(g_i,G_i)$, see (16.10)), and $E_Fg_l = 0$. The first element of $u^*_i - \Xi'_FZ_i = u_i$ (because $u^*_i = (u_i, u_{0i}g_i')$, the upper left $k \times k$ submatrix of $\tilde{V}_F$ equals $E_Fu^*_iZ_iZ_i' = E_Fg_I$, and so, $\lambda_{\max}(V_F) \geq \lambda_{\max}(E_Fg_lg_i')$, and $\inf_{F \in F} \lambda_{\max}(E_Fg_lg_i') > 0$ is implied by the last condition in $F$. This completes the verification of Assumption WU(c) in part (b) of the lemma.

Now, we prove part (b)(ii) of the lemma. We need to show that the four conditions in the definition of $F_{WU}$ in (16.12) hold for all $F \in F_P$, for some $\delta_1$ sufficiently small and some $M_1$ sufficiently large.

1. (I) & (II) We have $\inf_{F \in F_P} \lambda_{\min}(W_F) > 0$ and $\sup_{F \in F_P} ||W_F|| < \infty$ by the proofs of (I) and (II) for part (a)(ii) of the lemma and $F_P \subset F$.

2. (III) We show that $\inf_{F \in F_P} \lambda_{\min}(U_F) > 0$, where in the present case $U_F := U_1(U_2F) := ((\theta_0, I_p)(\Sigma^\varepsilon(\Omega_F, \tilde{R}_F))^{-1}(\theta_0, I_p'))^{1/2}$ and $\Sigma(\Omega_F, \tilde{R}_F)$ has $(j, \ell)$ element equal to $tr(\tilde{R}_{ji}^{'\ell}\Omega_{\ell}^{-1})/k$ (by (16.11)). The inequalities $E_F||Z_i||^{1+\gamma} \leq M$, $E_F||g_l', vec(G_i')'||^{2+\gamma} \leq M$, and $\lambda_{\min}(E_FZ_iZ_i') \geq \delta$ imply that $\sup_{F \in F_P} ||\Xi_F|| + ||E_Ff_if_j'|| + ||E_F(\Xi'_FZ_i\Xi_F \otimes Z_iZ_i')|| + ||E_F(g_l,G_i)\Xi_F \otimes Z_iZ_i'|| < \infty$, where $\Xi_F$ is defined in (16.10) (using the Cauchy-Bunyakovsky-Schwarz inequality). This, in turn, implies that $\sup_{F \in F_P} ||\tilde{V}_F|| < \infty$, $\sup_{F \in F_P} ||\tilde{R}_F|| < \infty$, $\sup_{F \in F_P} ||\tilde{F}_F|| < \infty$, $\sup_{F \in F_P} ||\tilde{F}_F|| < \infty$, and $\lambda_{\min}(\tilde{L}_F) \geq \delta_2$ for some $\delta_2 > 0$, where $\tilde{F}_F$ and $\tilde{R}_F$ are defined in (16.10). $\tilde{F}_F := (\theta_0, I_p)(\Sigma^\varepsilon_F)^{-1}(\theta_0, I_p')$, and $(\Sigma^\varepsilon_F)^{-1}$ exists by (IV) below (and $\lambda_{\min}(\tilde{L}_F) \geq \delta_2$ holds because $A := (\theta_0, I_p) \in R^{p \times (p+1)}$ has full row rank $p$ and $\lambda_{\min}(\tilde{L}_F) = \inf_{x \in R^p:||x|| = 1} A'A(\Sigma^\varepsilon_F)^{-1}A' \lambda \geq \inf_{x \in R^p:||x|| = 1} (A'\lambda)'(\Sigma^\varepsilon_F)^{-1}(A'\lambda)'||A'\lambda||^2 \times \inf_{x \in R^p:||x|| = 1} ||A'\lambda||^2 = \lambda_{\min}(\Sigma^\varepsilon_F)^{-1} \lambda_{\min}(AA') \geq \delta_2$ for some $\delta_2 > 0$ that does not depend on $F$). Finally, $\lambda_{\min}(\tilde{L}_F) \geq \delta_2$ implies the desired result that $\lambda_{\min}(U_F) \geq \delta_1$ for some $\delta_1 > 0$ (because $U_F := \tilde{L}_F^2$).

3. (IV) We show that $\sup_{F \in F_P} ||U_F|| < \infty$, where $U_F$ is as in (III) immediately above. The proof is the same as the proof of (IV) for part (a)(ii) of the lemma given above, but with $\tilde{R}_F$ in place of
and with the verification that \( \inf_{F \in \mathcal{F}} \lambda_{\max}(\tilde{R}_F) > 0 \) given in the the verification of Assumption WU(c) above.

Results (I)-(IV) establish the result of part (b)(ii) of the lemma. \( \square \)

### 27.6 Proof of Theorem 16.1 for the Anderson-Rubin Test and CS

**Proof of Theorem 16.1 for AR Test and CS.** We prove the AR test results of Theorem 16.1 by applying Proposition 16.3 with

\[
\lambda = \lambda_F := E_F g_i g_i' \quad \text{and} \quad \Lambda := \{ \lambda : \lambda = \lambda_F \text{ for some } F \in \mathcal{F}_{AR} \}. \tag{27.82}
\]

We define the parameter space \( H \) as in (16.2). For notational simplicity, we verify Assumption B* used in Proposition 16.3 for a sequence \( \{\lambda_n \in \Lambda : n \geq 1\} \) for which \( h_n(\lambda_n) \rightarrow h \in H \), rather than a subsequence \( \{\lambda_{w_n} \in \Lambda : n \geq 1\} \) for some subsequence \( \{w_n\} \) of \( \{n\} \). The same argument as given below applies with a subsequence \( \{\lambda_{w_n} : n \geq 1\} \). For the sequence \( \{\lambda_n \in \Lambda : n \geq 1\} \), we have

\[
\lambda_{F_n} \rightarrow h := \lim E_{F_n} g_i g_i'. \tag{27.83}
\]

The \( k \times k \) matrix \( h \) is pd because \( \lambda_{\min}(E_{F_n} g_i g_i') \geq \delta > 0 \) for all \( n \geq 1 \) (by the last condition in \( \mathcal{F}_{AR} \)) and \( \lim \lambda_{\min}(E_{F_n} g_i g_i') = \lambda_{\min}(h) \) (because the minimum eigenvalue of a matrix is a continuous function of the matrix).

By the multivariate central limit theorem for triangular arrays of row-wise i.i.d. random vectors with mean \( 0^k \), variance \( \lambda_{F_n} \) that satisfies \( \lambda_{F_n} \rightarrow h \), and uniformly bounded \( 2 + \gamma \) moments, we have

\[
n^{1/2} g_n \rightarrow_d h^{1/2} Z, \quad \text{where } Z \sim N(0^k, I_k). \tag{27.84}
\]

We have

\[
\tilde{\Omega}_n = n^{-1} \sum_{i=1}^{n} (g_i g_i' - E_{F_n} g_i g_i') - \tilde{g}_n \tilde{g}_n' + E_{F_n} g_i g_i' \rightarrow_p h \quad \text{and} \quad \tilde{\Omega}_n^{-1} \rightarrow_p h^{-1}, \tag{27.85}
\]

where the equality holds by definition of \( \tilde{\Omega}_n \) in (4.1), the first convergence result uses (27.83), (27.84), and the WLLN's for triangular arrays of row-wise i.i.d. random vectors with expectation that converges to \( h \), and uniformly bounded \( 1 + \gamma/2 \) moments, and the second convergence result holds by Slutsky’s Theorem because \( h \) is pd.

101
Lemma, we obtain the results of Theorems 7.1 and 15.3 using an argument that is similar to that of distributions $F$ statistic, which is based on general weight matrices $A_F$ and $G_i$. Theorem 15.3.

SR-CQLR semi-strong identification (Theorem 7.1 of AG2.

GRADE

In turn, (27.86) gives

$$P_{F_n}(AR_n > \chi^2_{k,1-\alpha}) \to P(Z'Z > \chi^2_{k,1-\alpha}) = \alpha.$$  (27.87)

where the equality holds because $\chi^2_{k,1-\alpha}$ is the $1 - \alpha$ quantile of $Z'Z$. Equation (27.87) verifies Assumption B' and the proof of the AR test results of Theorem 16.1 is complete.

The proof of the AR CS results of Theorem 16.1 is analogous to those for the tests, see the Comment to Proposition 16.3. □

28 Proofs of Theorems 7.1 and 15.3

Suppose $k \geq p$. Let $A_F$ and $\Pi_{1F}$ be defined as in (3.4) and (3.5) and the paragraph following these equations with $\theta = \theta_0$. Define $\lambda^{*,*}_F$, $\Lambda^*$, and $\{\lambda^{*,*}_{n,h} : n \geq 1\}$ as $\lambda_F$, $\Lambda_{WU}$, and $\{\lambda_{n,h} : n \geq 1\}$, respectively, are defined in (16.16)-(16.18), but with $g_i$ and $G_i$ replaced by $g^*_{Fi} := \Pi_{1F}^{-1/2} A_F' g_i$ and $G^*_{Fi} := \Pi_{1F}^{-1/2} A_F' G_i$, with $F$ replaced by $F^{SR}$, and with $W_F := W_1(W_{2F})$ and $U_F := U_1(U_{2F})$ defined as in (16.8) with $g_i$ and $G_i$ replaced by $g^*_F$ and $G^*_F$. In addition, we restrict $\{\lambda^{*,*}_{n,h} : n \geq 1\}$ to be a sequence for which $\lambda_{\min}(E_{F_n} g_i g_i') > 0$ for all $n \geq 1$. Let $(s^*_{1F_n}, ..., s^*_{pF_n})$ denote the singular values of $E_F G^*_F$. Under these conditions, $A_{F_n} = A_{F_n}^\Omega$, $\Pi_{1F} = \Pi_{F_n}$, $W_{F_n} := (\Pi_{1F}^{-1/2} A_F' \Omega_{F_n} A_{F_n} \Pi_{1F}^{-1/2})^{-1} = I_k$, and $n^{1/2} s^*_{pF_n} \to \infty$ iff $n^{1/2} s^*_{pF_n} \to \infty$.

Theorem 7.1 of AG2. Suppose $k \geq p$. For any sequence $\{\lambda^{*,*}_{n,h} : n \geq 1\}$ that exhibits strong or semi-strong identification (i.e., for which $n^{1/2} s^*_{pF_n} \to \infty$) and for which $\lambda^{*,*}_{n,h} \in \Lambda^* \ \forall n \geq 1$ for the SR-CQLR test statistic and critical value, we have

(a) $SR-QL_{R_F} = QLR_{R_F} + o_p(1) = LM_n + o_p(1) = LM^{GMM}_n + o_p(1)$ and

(b) $c_{k,p}(n^{1/2} \hat{D}^*_n, 1 - \alpha) \to_p \chi^2_{p,1-\alpha}.$

Theorem 15.3. Suppose $k \geq p$. For any sequence $\{\lambda^{*,*}_{n,h} : n \geq 1\}$ that exhibits strong or semi-strong identification (i.e., for which $n^{1/2} s^*_{pF_n} \to \infty$) and for which $\lambda^{*,*}_{n,h} \in \Lambda^* \ \forall n \geq 1$, we have

(a) $SR-QL_{R_{P_n}} = QLR_{P_n} + o_p(1) = LM_n + o_p(1) = LM^{GMM}_n + o_p(1)$ and

(b) $c_{k,p}(n^{1/2} \hat{D}^*_n, 1 - \alpha) \to_p \chi^2_{p,1-\alpha}.$

The proofs of Theorems 7.1 and 15.3 use the following Lemma that concerns the $QLR_{W,n}$ statistic, which is based on general weight matrices $\hat{W}_n$ and $\hat{U}_n$, see (16.3), and considers sequences of distributions $F$ in $\mathcal{F}$ or $\mathcal{F}_P$, rather than sequences in $\mathcal{F}^{SR}$ or $\mathcal{F}^{SR}_P$. Given the result of this Lemma, we obtain the results of Theorems 7.1 and 15.3 using an argument that is similar to that
employed in Section 17, combined with the verification of Assumption WU for the parameter spaces \( \Lambda_{WU} \) and \( \Lambda_{WU,P} \) for the CQLR and CQLRP tests, respectively, that is given in Lemma 27.4 in Section 27.

For the weight matrix \( \hat{W}_n \in R^{k \times k} \), Kleibergen’s LM statistic and the standard GMM LM statistic are defined by

\[
LM_n(\hat{W}_n) := n\hat{g}_n^2\hat{G}_n^{-1/2}P_{\hat{W}_n,D_n}\hat{G}_n^{-1/2}g_n \quad \text{and} \quad LM_n^{GMM}(\hat{W}_n) := n\hat{g}_n^2\hat{G}_n^{-1/2}P_{\hat{W}_n,G_n}\hat{G}_n^{-1/2}g_n, \tag{28.1}
\]

respectively, where \( \hat{G}_n \) is the sample Jacobian defined in (4.1) with \( \theta = \theta_0 \). In Lemma 28.1 we show that when \( n^{1/2}T_{pF_n} \to \infty \), the QLR_{WU,n} statistic is asymptotically equivalent to the \( LM_n(\hat{W}_n) \) and \( LM_n^{GMM}(\hat{W}_n) \) statistics.

The condition \( n^{1/2}T_{pF_n} \to \infty \) corresponds to strong or semi-strong identification in the present context. This holds because, for \( F \in F_{WU} \), the smallest and largest singular values of \( W_F(E_{FG_1}U_{F}) \) (i.e., \( \tau_{\min(k,p)} \) and \( \tau_{1F} \)) are related to those of \( \Omega_{F}^{-1/2}E_{FG_1} \), denoted (as in Section 6.2 of AG2) by \( s_{\min(k,p)} \) and \( s_{1F} \), via \( c_1s_{jF} \leq \tau_{jF} \leq c_2s_{jF} \) for \( j = \min\{k,p\} \) and \( j = 1 \) for some constants \( 0 < c_1 < c_2 < \infty \). This result uses the condition \( \lambda_{\min}(\Omega_F) \geq \delta > 0 \) in \( F_{WU} \). (See Section 10.3 in the SM to AG1 for the argument used to prove this result.) In consequence, when \( k \geq p \), the standard weak, nonstandard weak, semi-strong, and strong identification categories defined in Section 6.2 are unchanged if \( s_{jF_n} \) is replaced by \( \tau_{jF_n} \) in their definitions for \( j = 1,p \).

**Lemma 28.1** Suppose \( k \geq p \) and Assumption WU holds for some non-empty parameter space \( \Lambda_* \subset \Lambda_{WU} \). Under all sequences \( \{\lambda_{n,h} : n \geq 1\} \) with \( \lambda_{n,h} \in \Lambda_* \) for which \( n^{1/2}T_{pF_n} \to \infty \), we have

(a) \( QLR_{WU,n} = LM_n(\hat{W}_n) + o_p(1) = LM_n^{GMM}(\hat{W}_n) + o_p(1) \) and

(b) \( c_{k,p}(n^{1/2}\hat{W}_n\hat{D}_n\hat{U}_n, 1 - \alpha) \to p \chi^2_{p,1-\alpha} \).

**Comment:** The choice of the weight matrix \( \hat{U}_n \) that appears in the definition of the \( QLR_{WU,n} \) statistic, defined in (16.3), does not affect the asymptotic distribution of \( QLR_{WU,n} \) statistic under strong or semi-strong identification. This holds because \( QLR_{WU,n} \) is within \( o_p(1) \) of LM statistics that project onto the matrices \( \hat{W}_n\hat{D}_n\hat{U}_n \) and \( \hat{W}_n\hat{G}_n\hat{U}_n \), but such statistics do not depend on \( \hat{U}_n \) because \( P_{\hat{W}_n,D_n}\hat{U}_n = P_{\hat{W}_n,D_n} \) and \( P_{\hat{W}_n,G_n}\hat{U}_n = P_{\hat{W}_n,G_n} \) when \( \hat{U}_n \) is a nonsingular \( p \times p \) matrix. In consequence, the LM statistics that appear in Lemma 28.1 (and are defined in (28.1)) do not depend on \( \hat{U}_n \).

**Proofs of Theorem 7.1 of AG2 and Theorem 15.3.** By the second last paragraph of Section 5.2, \( SR-QLR_n(\theta_0) = QLR_n(\theta_0) \) \( wp \to 1 \) under any sequence \( \{F_n \in F_{SR} : n \geq 1\} \) with \( r_{F_n}(\theta_0) = k \) for \( n \) large. By the same argument as given there, \( SR-QLR_{P,n}(\theta_0) = QLR_{P,n}(\theta_0) \) \( wp \to 1 \) under any
sequence \( \{F_n \in \mathcal{F}^S_P : n \geq 1\} \) with \( r_{F_n}(\theta_0) = k \) for \( n \) large. This establishes the first equality in part (a) of Theorems 7.1 and 15.3 because by assumption \( \lambda_{\min}(E_{F_n}g_i g_i') > 0 \) for all \( n \geq 1 \) (see the paragraphs preceding Theorems 7.1 and 15.3).

Assumption WU for the parameter spaces \( \Lambda_{WU} \) and \( \Lambda_{WU,P} \) is verified in Lemma 27.4 in Section 27 for the CQLR and CQLR\_P tests, respectively. Hence, Lemma 28.1 implies that under sequences \( \{\lambda_{n,h} : n \geq 1\} \) we have \( QLR_n = LM_n(\hat{\Omega}_n^{-1/2}) + o_p(1) = LM_n^{GMM}(\hat{\Omega}_n^{-1/2}) + o_p(1) \) and likewise for \( QLR_{P_n} \), where \( QLR_n \) and \( QLR_{P_n} \) are defined in (5.7) and in the paragraph containing (15.7), respectively, and \( LM_n(\hat{\Omega}_n^{-1/2}) \) and \( LM_n^{GMM}(\hat{\Omega}_n^{-1/2}) \) are defined in (28.1) with \( \hat{W}_n = \hat{\Omega}_n^{-1/2} \). In addition, Lemma 28.1 implies that \( c_{k,p}(n^{1/2} \bar{D}^*_n, 1-\alpha) \rightarrow_p \chi^2_{p,1-\alpha} \) and \( c_{k,p}(n^{1/2} \bar{D}^*_n, 1-\alpha) \rightarrow_p \chi^2_{p,1-\alpha} \).

Note that all of these results are for sequences of distributions \( F \) in \( \mathcal{F} \) or \( \mathcal{F}_P \), not \( \mathcal{F}^{SR} \) or \( \mathcal{F}^{S_P} \).

Next, we employ a similar argument to that in (17.5)-(17.7) of Section 17. Specifically, we apply the version of Lemma 28.1 described in the previous paragraph with \( g^e_{F_i} := \Pi_{1F_i}^{-1/2} A^e_{F_i} g_i \) and \( G^*_{F_i} := \Pi_{1F_i}^{-1/2} A^e_{F_i} G_i \) in place of \( g_i \) and \( G_i \) to the \( QLR_n \) and \( QLR_{P_n} \) test statistics and their corresponding critical values. We have \( n^{1/2} s^*_p F_n \rightarrow \infty \) iff \( n^{1/2} \tau^*_p F_n \rightarrow \infty \), where \( s^*_p \) denotes the smallest singular value of \( E_F G^*_{F_i} \) and \( \tau^*_p \) is defined to be the smallest singular value of \( (E_F g^e_{F_i} g^e_{F_i})^{-1/2} (E_F G^*_{F_i}) U_F = (\Pi_{1F_i}^{-1/2} A^e_{F_i} \Omega_F A_F \Pi_{1F_i}^{-1/2})(E_F G^*_{F_i}) U_F \). In consequence, the condition \( n^{1/2} \tau^*_p F_n \rightarrow \infty \) of Lemma 28.1 holds for the transformed variables \( g^e_{F_i} \) and \( G^*_{F_i} \), i.e., \( n^{1/2} \tau^*_p F_n \rightarrow \infty \). In the present case, \( \{\Pi_{1F_n}^{-1/2} A^e_{F_n} : n \geq 1\} \) are nonsingular \( k \times k \) matrices by the assumption that \( \lambda_{\min}(E_{F_i} g_i g_i') > 0 \) for all \( n \geq 1 \) (as specified in the paragraphs preceding Theorems 7.1 and 15.3). In consequence, by Lemmas 5.1 and 15.1 the \( QLR_n \) and \( QLR_{P_n} \) test statistics and their corresponding critical values are exactly the same when based on \( g^e_{F_i} \) and \( G^*_{F_i} \) as when based on \( g_{F_i} \) and \( G_{F_i} \). By the definitions of \( \mathcal{F}^{SR} \) and \( \mathcal{F}^{S_P} \), the transformed variables \( g^e_{F_i} \) and \( G^*_{F_i} \) satisfy the conditions in \( \mathcal{F} \) and \( \mathcal{F}_P \), see (17.6) and (17.7). In particular, \( E_F g^e_{F_i} g^e_{F_i} = I_k \) and \( \lambda_{\min}(E_F Z^*_F Z^*_F) \geq 1/(2c) > 0 \), where \( Z^*_F := \Pi_{1F}^{-1/2} A^e_F Z_i \) and \( c \) is as in the definition of \( \mathcal{F}^{S_P} \) in (15.3). In addition, the \( LM_n \) and \( LM_n^{GMM} \) statistics are exactly the same when based on \( g^e_{F_i} \) and \( G^*_{F_i} \) as when based on \( g_{F_i} \) and \( G_{F_i} \). (This holds because, for any \( k \times k \) nonsingular matrix \( M \), such as \( M = \Pi_{1F}^{-1/2} A^e_F \), we have \( LM_n := n \hat{g}_n \hat{\Omega}_n^{-1/2} \hat{D}_n [\hat{D}^*_n \hat{\Omega}_n^{-1/2} \hat{D}_n]^{-1} \hat{D}_n \hat{\Omega}_n^{-1/2} \hat{g}_n = n \hat{g}_n M' (\hat{\Omega}_n M')^{-1} M \hat{D}_n [\hat{D}^*_n M' (\hat{\Omega}_n M')^{-1} M \hat{D}_n]^{-1} \hat{D}^*_n M' (\hat{\Omega}_n M')^{-1} \hat{g}_n \) and likewise for \( LM_n^{GMM} \).) Using these results, the version of Lemma 28.1 described in the previous paragraph applied to the transformed variables \( g^e_{F_i} \) and \( G^*_{F_i} \) establishes the second and third equalities of part (a) of Theorems 7.1 and 15.3 and part (b) of Theorems 7.1 and 15.3.

**Proof of Lemma 28.1.** We start by proving the first result of part (a) of the lemma. We have \( n^{1/2} \tau^*_p F_n \rightarrow \infty \) iff \( q = p \) (by the definition of \( q \) in (16.22)). Hence, by assumption, \( q = p \). Given this, \( Q^2_{2m}(\kappa) \) (defined in (26.11) in the proof of Theorem 16.6) is a scalar. In consequence, (26.13)
and (26.16) with $j = p + 1$ give

$$0 = |Q_{2n}^+(\hat{\kappa}_{(p+1)n})| = |M_{n,p+1-q}^+ - \hat{\kappa}_{(p+1)n}^+(1 + o_p(1))|$$

and, hence,

$$\hat{\kappa}_{(p+1)n}^+ = M_{n,p+1-q}^+(1 + o_p(1))$$

$$= (n^{1/2}B_{n,p+1-q}^{-1/2}U_n^T\hat{\Sigma}_n^{-1}D_{n}^+W_n)^{-1/2}h_{3,k-q}h_{3,k-q}^T(n^{1/2}W_n\hat{\Sigma}_n^{-1/2}g_n)(1 + o_p(1)) + o_p(1)$$

$$= (n^{1/2}g_n\hat{\Sigma}_n^{-1/2}h_{3,k-q}h_{3,k-q}^T)(1 + o_p(1)) + o_p(1)$$

$$= n\hat{g}_n\hat{\Sigma}_n^{-1/2}h_{3,k-q}h_{3,k-q}^T + o_p(1),$$

(28.2)

where $\hat{\kappa}_{(p+1)n}^+$ is defined in (26.2), the equality on the third line holds by the definition of $M_{n,p+1-q}^+$ in (26.16), the equality on the fourth line holds by lines two and three of (26.7) because when $q = p$ the third line of (26.7) becomes $n^{1/2}W_n\hat{\Sigma}_n^{-1/2}g_n$, i.e., $n^{1/2}W_n\hat{\Sigma}_n^{-1/2}g_n$ drops out, as noted near the end of the proof of Theorem 16.6, and the last equality holds because $W_n\hat{\Sigma}_n^{-1} = I_k + o_p(1)$ by Assumption WU and $n^{1/2}\hat{\Sigma}_n^{-1/2}g_n = o_p(1)$.

Next, we have

$$QLR_{WU,n} := AR_n - \lambda_{\min}(n\hat{Q}_{WU,n})$$

$$= AR_n - \hat{\kappa}_{(p+1)n}^+$$

$$= n\hat{g}_n\hat{\Sigma}_n^{-1/2}(I_k - h_{3,k-q}h_{3,k-q}^T) + o_p(1)$$

$$= n\hat{g}_n\hat{\Sigma}_n^{-1/2}h_{3,k-q}h_{3,k-q}^T + o_p(1),$$

(28.3)

where the first equality holds by the definition of $QLR_{WU,n}$ in (16.3), the second equality holds by the definition of $\hat{\kappa}_{(p+1)n}^+$ in (26.2), the third equality holds by (28.2) and the definition $AR_n := n\hat{g}_n\hat{\Sigma}_n^{-1}g_n$ in (4.2), and the last equality holds because $h_3 = (h_{3,q}, h_{3,k-q})$ is a $k \times k$ orthogonal matrix.

When $q = p$, by Lemma 16.4, we have

$$n^{1/2}W_n\hat{D}_nU_nT_n \rightarrow_d \bar{\Sigma}_h = h_{3,q}$$

$$n^{1/2}W_n\hat{D}_nU_nT_n \rightarrow_p h_{3,q},$$

(28.4)

where the equality holds by the definition of $\bar{\Sigma}_h$ in (16.24) when $q = p$ and the second convergence uses $W_n\hat{W}_n^{-1} = I_k + o_p(1)$ by Assumption WU. In consequence,

$$P_{W_n} = P_{n^{1/2}W_n\hat{D}_nU_nT_n} = P_{h_{3,q}} + o_p(1) = h_{3,q}h_{3,q}^T + o_p(1)$$

$$QLR_{WU,n} = LM_n(\hat{W}_n) + o_p(1),$$

(28.5)
where the first equality holds because \( n^{1/2}U_nT_n \) is nonsingular wp→1 by Assumption WU and post-multiplication by a nonsingular matrix does not affect the resulting projection matrix, the second equality holds by (28.4), the third equality holds because \( h_{3,q}^T h_{3,q} = I_q \) (since \( h_3 = (h_{3,q}, h_{3,k-q}) \) is an orthogonal matrix), and the second line holds by the first line, (28.3), \( n^{1/2} \tilde{G}_{n}^{-1/2} g_n = O_p(1) \), and the definition of \( LM_n(\tilde{W}_n) \) in (28.1).

As in (25.5) in Section 25 with \( \tilde{G}_n \) in place of \( \tilde{D}_n \), we have
\[
W_n \tilde{G}_n U_n B_{n,q} \tilde{\Sigma}_{n,q}^{-1} = W_n D_n U_n B_{n,q} \tilde{\Sigma}_{n,q}^{-1} + W_n n^{1/2}(\tilde{G}_n - D_n) U_n B_{n,q} (n^{1/2} \tilde{\Sigma}_{n,q})^{-1}
= C_{n,q} + o_p(1) \rightarrow_p h_{3,q},
\]
(28.6)
where \( D_n := E_{F_n} G_i \), the second equality uses (among other things) \( n^{1/2} \tau_{jF_n} \rightarrow \infty \) for all \( j \leq q \) (by the definition of \( q \) in (16.22)). The convergence in (28.6) holds by (16.19), (16.24), and (25.1). Using (28.6) in place of the first line of (28.4), the proof of \( QLR_{W,n} = LM_{n}^{GMM}(\tilde{W}_n) + o_p(1) \) is the same as that given for \( QLR_{W,n} = LM_{n}(\tilde{W}_n) + o_p(1) \). This completes the proof of part (a) of Lemma 28.1.

By (27.10) in the proof of Theorem 27.1 we have
\[
c_{k,p}(n^{1/2} \tilde{W}_n \tilde{D}_n \tilde{\Sigma}_n, 1 - \alpha) \rightarrow_d c_{k,p,q}(\tau_{[2] h}, 1 - \alpha) \quad \text{and} \quad c_{k,p,q}(\tau_{[2] h}, 1 - \alpha) = \chi^2_{p,1-\alpha} \quad \text{when} \quad q = p,
\]
(28.7)
where the second line of (28.7) holds by the sentence following (27.9). This proves part (b) of Lemma 28.1 because convergence in distribution to a constant is equivalent to convergence in probability to the same constant. □

29 Proofs of Lemmas 19.1, 19.2, and 19.3

29.1 Proof of Lemma 19.1

Lemma 19.1. Suppose Assumption HLIV holds. Under the null hypothesis \( H_0 : \theta = \theta_0 \), for any sequence of reduced-form parameters \( \{\pi_n \in \Pi : n \geq 1\} \) and any \( p \geq 1 \), we have: (a) \( \tilde{R}_n \rightarrow_p \Sigma_V \otimes K_Z \), (b) \( \tilde{G}_n \rightarrow_p (b_0' \Sigma_V b_0) K_Z \), where \( b_0 := (1, -\theta_0)' \), (c) \( \tilde{\Sigma}_n \rightarrow_p (b_0' \Sigma_V b_0)^{-1} \Sigma_V \), (d) \( \tilde{\Sigma}_n^e \rightarrow_p (b_0' \Sigma_V b_0)^{-1} \Sigma_V \), (e) \( n^{1/2} \tilde{G}_{n}^{-1/2} g_n = \tilde{S}_n + o_p(1) \), and (f) \( n^{1/2} \tilde{D}_{n}^e = -(I_k + o_p(1)) T_n (I_p + o_p(1)) + o_p(1) \).

In this section, we suppress the dependence of various quantities on \( \theta_0 \) for notational simplicity. Thus, \( g_i := g_i(\theta_0) \), \( G_i := G_i(\theta_0) = (G_{i1}, \ldots, G_{ip}) \in \mathbb{R}^{k \times p} \), and similarly for \( \tilde{g}_n \), \( \tilde{G}_n \), \( f_i \), \( B \), \( \tilde{D}_n \), \( \tilde{G}_{jn} \), \( \tilde{\Sigma}_n \), \( \tilde{R}_n \), \( \tilde{D}_{n}^e \), and \( \tilde{L}_n \).
The proof of Lemma 19.1 uses the following lemmas. Define

\[ A_0^* := \Sigma V B \left( b'_0 \Sigma V^2 c_0, \ldots, b'_0 \Sigma V^{p+1} c_0 \right) \in R^{(p+1) \times p}, \quad B := \begin{pmatrix} 1 & 0'_p \\ -\theta_0 & -I_p \end{pmatrix} \in R^{(p+1) \times (p+1)}, \]

\[ c_0 := (b'_0 \Sigma V b_0)^{-1} b_0 := (1, -\theta'_0)' \], \quad (\Sigma V_1, \ldots, \Sigma V_{p+1}) := \Sigma V \in R^{(p+1) \times (p+1)}, \quad L_{V0} := (\theta_0, I_p) \Sigma V^{-1} (\theta_0, I_p)' \in R^{p \times p}. \] (29.1)

As defined in (19.4), \( A_0 := (\theta_0, I_p)' \in R^{(p+1) \times p}. \)

**Lemma 29.1** \( A_0^* L_{V0} = -A_0. \)

**Comment:** Some calculations show that the columns of \( A_0^* \) and \( A_0 \) are all orthogonal to \( b_0 \). Also, \( A_0^* \) and \( A_0 \) both have full column rank \( p \). Hence, the columns of \( A_0^* \) and \( A_0 \) span the same space in \( R^{p+1} \). It is for this reason that there exists a \( p \times p \) positive definite matrix \( L = L_{V0} \) that solves \( A_0^* L = -A_0. \)

**Lemma 29.2** Suppose Assumption HLIV holds. Under \( H_0 \), we have (a) \( n^{1/2} \tilde{g}_n \rightarrow_d N(0^k, b'_0 \Sigma V b_0 \cdot K_Z) \), (b) \( n^{-1} \sum_{i=1}^n (G_{ij} g'_i - E G_{ij} g'_i) = o_p(1) \) \( \forall j \leq p \), (c) \( \tilde{G}_n = O_p(1) \), (d) \( n^{-1} \sum_{i=1}^n (g'_i - Eg'_i) = o_p(1) \), and (e) \( \tilde{G}_n - n^{-1} \sum_{i=1}^n E G_i = O_p(n^{-1/2}). \)

**Proof of Lemma 19.1.** To prove part (a), we determine the probability limit of \( \tilde{V}_n \) defined in (15.5). By (15.5) and (19.1)-(19.3), in the linear IV regression model with reduced-form parameter \( \pi_n \), we have

\[ u_i := u_i(\theta_0) = y_{i1} - Y_{2i} \theta_0, \quad E u_i = 0, \quad u_{\theta i} = -Y_{2i} = -\pi'_n Z_i - V_{2i}, \quad E u_{\theta i} = -\pi'_n Z_i, \]

\[ u_i^* := \begin{pmatrix} u_i \\ u_{\theta i} \end{pmatrix} = \begin{pmatrix} u_i \\ -Y_{2i} \end{pmatrix} = \Xi_n' Z_i + \begin{pmatrix} u_i \\ -V_{2i} \end{pmatrix}, \quad \text{where } \Xi_n = (0^k, -\pi_n) \in R^{k \times (p+1)}, \]

\[ E u_i^* = \Xi_n' Z_i, \quad u_i^* - E u_i^* = \begin{pmatrix} u_i \\ -V_{2i} \end{pmatrix} = B' V_i, \quad \hat{\mu}_{in}^* - E u_i^* = (\Xi_n - \Xi_n)' Z_i, \quad \text{and} \]

\[ U^* := (u_1^*, \ldots, u_n^*)' = Z_{n \times k} \Xi_n + VB, \quad \text{where } V := (V_1, \ldots, V_n)' \in R^{n \times (p+1)} \] (29.2)

and \( B := B(\theta_0) \) is defined in (15.5).

Next, we have

\[ \Xi_n - \Xi_n = (Z'_{n \times k} Z_{n \times k})^{-1} Z'_{n \times k} U^* - \Xi_n = (n^{-1} Z'_{n \times k} Z_{n \times k})^{-1} n^{-1} Z'_{n \times k} VB = O_p(n^{-1/2}), \] (29.3)
where the first equality holds by the definition of $\overline{\Xi}_n$ in \([15.5]\), the second equality uses the last line of \([29.2]\), and the third equality holds by Assumption HLIV(c) (specifically, $n^{-1}Z'_{n\times k}Z_{n\times k} \to K_Z$ and $K_Z$ is pd) and by $n^{-1/2}Z'_{n\times k}V = O_p(1)$ (which holds because $EZ'_{n\times k}V = 0$ and the variance of the $(j, \ell)$ element of $n^{-1/2}Z'_{n\times k}V$ is $n^{-1}\sum_{i=1}^n Z_{ij}^2 EV_{i\ell}^2 \to K_{Zjj}EV_{i\ell}^2 < \infty$ using Assumption HLIV(c), where $K_{Zjj}$ denotes the $(j, j)$ element of $K_Z$, for all $j \leq k, \ell \leq p + 1$).

By the definition of $\tilde{V}_n$ in \([15.5]\) and simple algebra, we have

\[
\tilde{V}_n := n^{-1} \sum_{i=1}^n [(u_i^* - \hat{u}_{in}^*) (u_i^* - \hat{u}_{in}^*)' \otimes Z_iZ_i']
\]

\[
= n^{-1} \sum_{i=1}^n [(u_i^* - Eu_i^*) (u_i^* - Eu_i^*)' \otimes Z_iZ_i'] - n^{-1} \sum_{i=1}^n [(\hat{u}_{in}^* - Eu_i^*) (u_i^* - Eu_i^*)' \otimes Z_iZ_i']
\]

\[
- n^{-1} \sum_{i=1}^n [(u_i^* - Eu_i^*) (\hat{u}_{in}^* - Eu_i^*)' \otimes Z_iZ_i'] + n^{-1} \sum_{i=1}^n [(\hat{u}_{in}^* - Eu_i^*) (\hat{u}_{in}^* - Eu_i^*)' \otimes Z_iZ_i'].
\]

Using the third line of \([29.2]\), the fourth summand on the rhs of \([29.4]\) equals

\[
n^{-1} \sum_{i=1}^n \left[(\overline{\Xi}_n - \Xi_n)' \otimes Z_iZ_i' (\overline{\Xi}_n - \Xi_n) \otimes Z_iZ_i'\right].
\]

The elements of the fourth summand on the rhs of \([29.4]\) are each $o_p(1)$ because each is bounded by $O_p(n^{-1})n^{-1} \sum_{i=1}^n ||Z_i||^4$ using \([29.3]\) and $n^{-1} \sum_{i=1}^n ||Z_i||^4 \leq n^{-1} \sum_{i=1}^n ||Z_i||^41(||Z_i|| > 1) + 1 \leq n^{-1} \sum_{i=1}^n ||Z_i||^6 + 1 = o(n)$ by Assumption HLIV(c).

Using the third line of \([29.2]\), the second summand on the rhs of \([29.4]\) (excluding the minus sign) equals

\[
n^{-1} \sum_{i=1}^n \left[(\overline{\Xi}_n - \Xi_n)' \otimes Z_iV_i' B \otimes Z_iZ_i'\right].
\]

The elements of the second summand on the rhs of \([29.4]\) are each $o_p(1)$ because $\overline{\Xi}_n - \Xi_n = O_p(n^{-1/2})$ by \([29.3]\) and for any $j_1, j_2, j_3 \leq k$ and $\ell \leq p$ we have $n^{-1} \sum_{i=1}^n Z_{ij_1}Z_{ij_2}Z_{ij_3} V_{i\ell} = o_p(n^{1/2})$ because its mean is zero and its variance is $EV_{i\ell}^2 n^{-1} \sum_{i=1}^n Z_{ij_1}Z_{ij_2}Z_{ij_3}^2 = o(n)$ by Assumption HLIV(c). By the same argument, the elements of the third summand on the rhs of \([29.4]\) are each $o_p(1)$. 

108
In consequence, we have

\[ \tilde{V}_n = n^{-1} \sum_{i=1}^{n} [B'V_iV'_i B \otimes Z_i Z'_i] + o_p(1) \]

\[ = n^{-1} \sum_{i=1}^{n} [(B'V_iV'_i B - B'S_{V}B) \otimes Z_i Z'_i] + \left[ B'S_{V}B \otimes n^{-1} \sum_{i=1}^{n} Z_i Z'_i \right] + o_p(1) \]

\[ \rightarrow_p B'S_{V}B \otimes K_Z, \tag{29.7} \]

where the first equality holds using (29.4), the argument in the two paragraphs following (29.4), and the third line of (29.2), the second equality holds by adding and subtracting the same quantity, and the convergence holds by Assumption HLIV(c) (specifically, \( n^{-1} \sum_{i=1}^{n} Z_i Z'_i \rightarrow K_Z \)) and because the first summand on the second line is \( o_p(1) \) (which holds because it has mean zero and each of its elements has variance that is bounded by \( O(n^{-2} \sum_{i=1}^{n} \|Z_i\|^4) = o(1) \), where the latter equality holds by the calculations following (29.5)).

Equation (29.7) gives

\[ \tilde{R}_n := (B' \otimes I_k) \tilde{V}_n (B \otimes I_k) \rightarrow_p \Sigma_{V} \otimes K_Z \tag{29.8} \]

because \( B'B = BB = I_{p+1} \). Hence, part (a) holds.

To prove part (b), we have

\[ \hat{\Omega}_n := n^{-1} \sum_{i=1}^{n} g_i g'_i - \tilde{g}_n \tilde{g}_n = n^{-1} \sum_{i=1}^{n} Eg_i g'_i + n^{-1} \sum_{i=1}^{n} (g_i g'_i - Eg_i g'_i) + O_p(n^{-1}) \]

\[ = n^{-1} \sum_{i=1}^{n} Z_i Z'_i E u^2_i + o_p(1) \rightarrow_p (b'_0 \Sigma_{V} b_0) K_Z, \tag{29.9} \]

where the first equality holds by the definition in (4.1), second equality uses \( n^{1/2} \tilde{g}_n = O_p(1) \) by Lemma [29.2(a)], the third equality holds by Lemma [29.2(d)], and the convergence holds by Assumption HLIV(c) and because \( E u^2_i = E (V'_i b_0)^2 = b'_0 \Sigma_{V} b_0 \) by Assumption HLIV(b).

Part (c) holds because

\[ \tilde{\Sigma}_{j\ell n} = tr(\tilde{R}_{j\ell n} \tilde{\Omega}_n^{-1})/k \rightarrow_p tr(\Sigma_{Vj} \Sigma_{\ell}^{-1} K_Z (b'_0 \Sigma_{V} b_0)^{-1} K_Z^{-1})/k = \Sigma_{Vj} (b'_0 \Sigma_{V} b_0)^{-1}, \tag{29.10} \]

where \( \tilde{\Sigma}_{j\ell n} \) and \( \Sigma_{Vj} \) denote the \((j, \ell)\) elements of \( \tilde{\Sigma}_n \) and \( \Sigma_{V} \), respectively, \( \tilde{R}_{j\ell n} \) denotes the \((j, \ell)\) submatrix of \( \tilde{R}_n \) of dimension \( k \times k \), and the convergence holds because \( \tilde{R}_{j\ell n} \rightarrow_p \Sigma_{Vj} \Sigma_{\ell}^{-1} K_Z \) for \( j, \ell = 1, \ldots, p+1 \) and \( \tilde{\Omega}_n \rightarrow_p (b'_0 \Sigma_{V} b_0) K_Z \) by parts (a) and (b) of the lemma.

Part (d) holds because \( \tilde{\Sigma}_n \rightarrow_p ((b'_0 \Sigma_{V} b_0)^{-1} \Sigma_{V})^c \) by part (c) of the lemma and Lemma [22.1(e)].
\[(b_0'\Sigma Vb_0)^{-1}\Sigma V = (b_0'\Sigma Vb_0)^{-1}\Sigma V \text{ by Lemma 22.1(d), and } \Sigma V = \Sigma V \text{ by Assumption HLIV(e) and Comment (ii) to Lemma 22.1.} \]

We prove part (f) next. We have

\[
n^{-1}Z'_{n\times k}Y = \left(n^{-1}\sum_{i=1}^{n}Z_i(y_{1i} - Y_{2i}^0\theta_0) + n^{-1}\sum_{i=1}^{n}Z_i'Y_{2i}\theta_0, n^{-1}\sum_{i=1}^{n}Z_iY_{2i}\right)
\]

where the expressions for \(\tilde{g}_n\) and \(\hat{G}_n\) use (19.3). Using (29.11) and the definition of \(L_{V0}\) in (29.1), the statistic \(T_n\) defined in (19.4) can be written as

\[
T_n := (Z'_{n\times k}Z_{n\times k})^{-1/2}Z'_{n\times k}Y\Sigma V^{-1}A_0(A_0'\Sigma V^{-1}A_0)^{-1/2}
\]

\[
n^{-1/2}(n^{-1}Z'_{n\times k}Z_{n\times k})^{-1/2}(\tilde{g}_n, \hat{G}_n)B\Sigma V^{-1}A_0L_{V0}^{-1/2}.
\]

Note that, using the definitions of \(B\) and \(L_{V0}\) in (29.1) and \(A_0\) in (19.4), the rhs expression for \(T_n\) equals the expression in (19.4).

Now we simplify the statistic \(\hat{D}_n := (\hat{D}_{1n}, \ldots, \hat{D}_{pn})\), where \(\hat{D}_{jn} := \hat{G}_{jn} - \hat{\Gamma}_{jn}\hat{\Omega}_n^{-1}\tilde{g}_n\), for \(j = 1, \ldots, p\), by replacing \(\hat{\Gamma}_{jn}\) and \(\hat{\Omega}_n\) by their probability limits plus \(o_p(1)\) terms. Let \(\pi_n := (\pi_{1n}, \ldots, \pi_{pn}) \in R^{k\times p}\). For \(j = 1, \ldots, p\), we have

\[
\hat{\Gamma}_{jn} := n^{-1}\sum_{i=1}^{n}(G_{ij} - \hat{G}_{jn})g_i' = n^{-1}\sum_{i=1}^{n}EG_{ij}g_i' + n^{-1}\sum_{i=1}^{n}(G_{ij}g_i' - EG_{ij}g_i') - \hat{G}_{jn}\tilde{g}_n
\]

\[
= n^{-1}\sum_{i=1}^{n}EG_{ij}g_i' + o_p(1) = -n^{-1}\sum_{i=1}^{n}EZ_iY_{2ij}Z_i'u_i + o_p(1)
\]

\[
= -n^{-1}\sum_{i=1}^{n}Z_iZ_i'EV_{2ij}V_i'b_0 + n^{-1}\sum_{i=1}^{n}Z_iZ_i'(Z_i'\pi_{jn})Eu_i + o_p(1)
\]

\[
= -n^{-1}\sum_{i=1}^{n}Z_iZ_i'S_{V,j+1}b_0 + o_p(1),
\]

where \(g_i = Z_i(y_{1i} - Y_{2i}^0\theta_0) = Z_iu_i\) by (19.3), the third equality holds by Lemma 29.2(a)-(c), the fourth equality holds by (19.3) with \(\theta = \theta_0\), the fifth equality uses \(Y_{2ij} = Z_i'\pi_{jn} + V_{2ij}\) and \(u_i = V_i'b_0\), and the sixth equality holds because \(EV_i = 0\) by Assumption HLIV(b), \(u_i = V_i'b_0\), and \(\Sigma V := (\Sigma_{V1}, \ldots, \Sigma_{VP+1}) := EV_iV_i'\).
Equations (29.9) and (29.13) give

\[ \tilde{D}_j := \tilde{G}_{jn} - \Gamma_{jn} \tilde{\Omega}_n^{-1} \tilde{g}_n = \tilde{G}_{jn} + \Sigma'_{V,j+1} b_0 (b_0' \Sigma_V b_0)^{-1} \tilde{g}_n + o_p(n^{-1/2}) \text{ and} \]

\[ \tilde{D}_n := (\tilde{D}_{1n}, ..., \tilde{D}_{pn}) = (\tilde{g}_n, \tilde{G}_n) \left( \begin{array}{c} \Sigma'_V b_0 c_0, ..., \Sigma'_{V,p+1} b_0 c_0 \\ I_p \end{array} \right) + o_p(n^{-1/2}) \]

\[ = (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} \left( \Sigma_V B \left( \begin{array}{c} \Sigma'_V b_0 c_0, ..., \Sigma'_{V,p+1} b_0 c_0 \\ I_p \end{array} \right) \right) + o_p(n^{-1/2}) \]

\[ = (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0^* + o_p(n^{-1/2}), \tag{29.14} \]

where the second equality on the first line uses \( \tilde{g}_n = O_p(n^{-1/2}) \) by Lemma 29.2(a), the second line uses \( c_0 = (b_0' \Sigma_V b_0)^{-1} \), the second last equality holds because \( B^{-1} = B \), and the last equality holds by the definition of \( A_0^* \) in (29.1).

Now, we have

\[ n^{1/2} \tilde{D}_n^* := n^{1/2} \tilde{\Omega}_n^{-1/2} \tilde{D}_n \tilde{\Omega}_n^{1/2} \]

\[ = (b_0' \Sigma_V b_0)^{-1/2} (I_k + o_p(1))(n^{-1} Z'_{n \times k} Z_{n \times k})^{-1/2} n^{1/2} (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0^* \]

\[ \times (b_0' \Sigma_V b_0)^{1/2} L_{V_0}^{1/2} (I_p + o_p(1)) + o_p(1) \]

\[ = -(I_k + o_p(1))(n^{-1} Z'_{n \times k} Z_{n \times k})^{-1/2} n^{1/2} (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0 L_{V_0}^{-1/2} (I_p + o_p(1)) + o_p(1) \]

\[ = -(I_k + o_p(1))(\tilde{\Omega}_n (I_p + o_p(1)) + o_p(1), \tag{29.15} \]

where the first equality holds by the definition of \( \tilde{D}_n^* \) in (5.7), the second equality holds by (29.14), \( \tilde{\Omega}_n \to_p (b_0' \Sigma_V b_0) K_Z \) (which holds by part (b) of the lemma), and \( \tilde{\Omega}_n := (\theta_0, I_p) (\Sigma_n^\varepsilon)^{-1} (\theta_0, I_p)' \to_p (b_0' \Sigma_V b_0) L_{V_0} \) (which holds because \( \Sigma_n^\varepsilon \to_p (b_0' \Sigma_V b_0)^{-1} \Sigma_V \) by part (d) of the lemma), for \( L_{V_0} := (\theta_0, I_p) (\Sigma_V)^{-1} (\theta_0, I_p)' \) defined in (29.1), the third equality holds by Lemma 29.1, and the last equality holds by (29.12). This completes the proof of part (f).

Lastly, we prove part (e). The statistic \( \overline{S}_n \) satisfies

\[ \overline{S}_n := (Z'_{n \times k} Z_{n \times k})^{-1/2} Z'_{n \times k} Y b_0 (b_0' \Sigma_V b_0)^{-1/2} \]

\[ = n^{1/2} (n^{-1} \sum_{i=1}^n Z_i Z_i')^{-1/2} \tilde{g}_n (b_0' \Sigma_V b_0)^{-1/2} \]

\[ = n^{1/2} \tilde{\Omega}_n^{-1/2} \tilde{g}_n + o_p(1), \tag{29.16} \]

where the first equality holds by the definition of \( \overline{S}_n \) in (19.4), the second equality holds because \( Y_i' b_0 = u_i \), and the third equality holds by (29.9) and \( n^{1/2} \tilde{g}_n = O_p(1) \) by Lemma 29.2(a). This proves part (e). □
Proof of Lemma 29.1. By pre-multiplying by $B\Sigma_V^{-1}$, the equation $A_0^*L_{V0} = -A_0$ is seen to be equivalent to

$$
\begin{pmatrix}
  b_0' \Sigma_{V2} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0 \\
  I_p
\end{pmatrix}
L_{V0} = -B \Sigma_V^{-1}
\begin{pmatrix}
  \theta_0' \\
  \Sigma_V^{-1}
\end{pmatrix}
= \begin{pmatrix}
  -1 & 0^{p'} \\
  \theta_0 & I_p
\end{pmatrix}
\begin{pmatrix}
  \theta_0' \\
  I_p
\end{pmatrix}.
$$

(29.17)

The last $p$ rows of these $p + 1$ equations are

$$
L_{V0} = (\theta_0, I_p)^{-1}(\theta_0, I_p)',
$$

(29.18)

which hold by the definition of $L_{V0}$ in (29.1).

Substituting in the definition of $L_{V0}$, the first row of the equations in (29.17) is

$$
(b_0' \Sigma_{V2} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0)(\theta_0, I_p)^{-1}(\theta_0, I_p)' = (-1, 0^{p'}) \Sigma_V^{-1}(\theta_0, I_p)'.
$$

(29.19)

Equation (29.19) holds by the following argument. Write $\Sigma_V := (\Sigma_{V1}, \Sigma_{V2}^*)$ for $\Sigma_{V2}^* \in R^{(p+1) \times p}$. Then, $b_0' \Sigma_{V2} \theta_0 = -b_0' \Sigma_{V} b_0 + b_0' \Sigma_{V1}$, since $b_0 := (1, -\theta_0)'$. The left-hand side of (29.19) equals

$$
\begin{align*}
(b_0' \Sigma_{V2}^* \theta_0 c_0, b_0' \Sigma_{V2} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0) & \Sigma_V^{-1}(\theta_0, I_p)', \\
& = ((-b_0' \Sigma_{V} b_0 + b_0' \Sigma_{V1}) c_0, b_0' \Sigma_{V2} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0) \Sigma_V^{-1}(\theta_0, I_p)', \\
& = (-1 + b_0' \Sigma_{V1} c_0, b_0' \Sigma_{V2} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0) \Sigma_V^{-1}(\theta_0, I_p)', \\
& = (-1 + b_0' \Sigma_{V1} c_0, b_0' \Sigma_{V2} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0) \Sigma_V^{-1}(\theta_0, I_p)',
\end{align*}
$$

(29.20)

where the second equality uses the definition of $c_0$ in (29.1).

Hence, the difference between the left-hand side (lhs) and the rhs of (29.19) equals

$$
(b_0' \Sigma_{V1} c_0, \ldots, b_0' \Sigma_{Vp+1} c_0) \Sigma_V^{-1}(\theta_0, I_p)' = c_0 b_0' \Sigma_{V} \Sigma_V^{-1}
\begin{pmatrix}
  \theta_0' \\
  I_p
\end{pmatrix} = 0_p'.
$$

(29.21)

using $b_0' := (1, -\theta_0')$. Thus, (29.19) holds, which completes the proof. □

Proof of Lemma 29.2. Part (a) holds by the CLT of Eicker (1963, Thm. 3) and the Cramér-Wold device under Assumptions IIIIV(a)-(c) because $n^{1/2}\tilde{g}_n = n^{-1} \sum_{i=1}^{n} Z_i u_i$ is an average of i.i.d. mean-zero finite-variance random variables $u_i$ with nonrandom weights $Z_i$. 

112
To show part (b), we write

\[ n^{-1} \sum_{i=1}^{n} (G_{ij} g_i' - EG_{ij} g_i') = -n^{-1} \sum_{i=1}^{n} Z_i Z_i'(Y_{2ij} u_i - EY_{2ij} u_i) \]

\[ = -n^{-1} \sum_{i=1}^{n} Z_i Z_i'(Z_i' \pi_j) u_i - n^{-1} \sum_{i=1}^{n} Z_i Z_i'(V_{2ij} u_i - \Sigma_{V_{j+1}} b_0), \]

(29.22)

where the first equality holds because \( g_i = Z_i u_i \) and \( G_{ij} = -Z_i Y_{2ij} \), the second equality holds because \( Y_{2ij} = Z_i' \pi_j + V_{2ij} \) and \( EV_{2ij} u_i = EV_{2ij} V_i' b_0 = \Sigma_{V_{j+1}} b_0 \). Both summands on the rhs have mean zero. The \( (\ell_1, \ell_2) \) element of the first summand has variance equal to \( n^{-2} \sum_{i=1}^{n} (Z_{i\ell_1} Z_{i\ell_2} Z_i' \pi_j)^2 \times Var(\ell_1, \ell_2) \), which converges to zero for all \( \ell_1, \ell_2 \leq k \) because \( n^{-1} \sum_{i=1}^{n} ||Z_i||^6 = o(n) \), \( Var(\ell_1, \ell_2) = b_0^2 \Sigma V b_0 < \infty, \) and \( sup_{j \leq p, n \geq 1} ||\pi_j|| < \infty \) by Assumption HLIV(b)-(d). The \( (\ell_1, \ell_2) \) element of the second summand has variance equal to \( n^{-2} \sum_{i=1}^{n} Z_{i\ell_1} Z_{i\ell_2} Z_i' V \), which converges to zero for all \( \ell_1, \ell_2 \leq k \) because \( n^{-1} \sum_{i=1}^{n} ||Z_i||^6 = o(n) \) and \( Var(V_{2ij} u_i) \leq E(V_{2ij} V_i' b_0)^2 \leq b_0' b_0 E||V_i||^4 < \infty \) by Assumptions HLIV(b)-(c). This establishes part (b).

For part (c), we have

\[ \hat{G}_n = -n^{-1} \sum_{i=1}^{n} Z_i Y_{2i}' = -n^{-1} \sum_{i=1}^{n} Z_i Z_i' \pi_j - n^{-1} \sum_{i=1}^{n} Z_i V_{2i}'. \]

(29.23)

The first term on the rhs is \( O(1) \) by Assumption HLIV(c)-(d). The second term on the rhs is \( O_p(n^{-1/2}) \) \((= o_p(1)) \) because it has mean zero and its \((\ell, j) \) element for \( \ell \leq k \) and \( j \leq p \) has variance \( n^{-2} \sum_{i=1}^{n} Z_i^2 \Sigma V_{j'} j' \), where \( \Sigma V_{j'} j' < \infty \) is the \((j', j') \) element of \( \Sigma V \) and \( j' = j + 1 \), and \( n^{-1} \sum_{i=1}^{n} Z_i^2 \Sigma V_{j'} j' \to K \), where \( K \to \infty \) is the \((\ell, \ell) \) element of \( K \). Hence, the rhs is \( O_p(1) \), which establishes part (c).

To prove part (d), we have

\[ n^{-1} \sum_{i=1}^{n} (g_i g_i' - EG_i g_i') = n^{-1} \sum_{i=1}^{n} Z_i Z_i'(u_i^2 - Eu_i^2) \to_p 0, \]

(29.24)

where the convergence holds because the rhs of the equality has mean zero and its \((\ell_1, \ell_2) \) element has variance equal to \( n^{-1} \sum_{i=1}^{n} (Z_{i\ell_1} Z_{i\ell_2} Z_i' V)^2 \times Var((V_i' b_0)^2) \leq n^{-1} \sum_{i=1}^{n} ||Z_i||^4 E||V_i||^4 ||b_0||^4 \times \infty \) by Assumption HLIV(b)-(c) for all \( \ell_1, \ell_2 \leq k \). This proves part (d).

Part (e) holds by the following argument:

\[ \hat{G}_n - n^{-1} \sum_{i=1}^{n} EG_i = -n^{-1} \sum_{i=1}^{n} Z_i (Y_{2i} - EY_{2i})' = -n^{-1} \sum_{i=1}^{n} Z_i V_{2i}' \to P(n^{-1/2}), \]

(29.25)

where the last equality holds by the argument following \( (29.23) \). \( \square \)

113
29.2 Proof of Lemma 19.2

Lemma 19.2 Suppose Assumptions HLIV and HLIV2 hold. Under the null hypothesis \( H_0 : \theta = \theta_0 \) and any \( p \geq 1 \), we have: (a) \( \hat{R}_n \to_p R(\pi_*) \), (b) \( \hat{\Sigma}_n \to_p (b_0'\Sigma_V b_0)^{-1}\Sigma_{V*} \), (c) \( \hat{\Sigma}_n \to_p (b_0'\Sigma_V b_0)^{-1}\Sigma_{V*} \), and (d) \( n^{1/2} \hat{D}_n^* = -(I_k + o_p(1))T_n(LV_0^{-1/2}L_{V*} + o_p(1)) + o_p(1) \), where \( LV_0 := (\theta_0, I_p)\Sigma_V^{-1}(\theta_0, I_p)' \in R^{p \times p} \) and \( LV_* := (\theta_0, I_p)\Sigma_V^{-1}(\theta_0, I_p)' \in R^{p \times p} \).

Proof of Lemma 19.2 To prove part (a), we determine the probability limit of \( \hat{V}_n \) defined in (5.3), where \( f_i = (Z_i'u_i, -vec(Z_iV_{2i}'))' \) by (19.1) and (19.3). For \( \zeta_n(\pi) \) defined in (19.6), we can write

\[
\zeta_n(\pi_n) = n^{-1}\sum_{i=1}^n Z_{ni}'Z_{ni}, \quad \text{where} \quad Z_{ni}' := vec\left(Z_iZ_i'\pi_n - n^{-1}\sum_{\ell=1}^n Z_iZ_{\ell}'\pi_n\right) = (\pi_n' \otimes Z_i)Z_i - n^{-1}\sum_{\ell=1}^n (\pi_n' \otimes Z_\ell)Z_\ell \in R^{kp}
\]

and the second equality in the second line follows from \( vec(ABC) = (C' \otimes A)vec(B) \).

We have

\[
\hat{V}_n := n^{-1}\sum_{i=1}^n \left( f_i - n^{-1}\sum_{\ell=1}^n E_{f_\ell} \right) \left( f_i - n^{-1}\sum_{\ell=1}^n E_{f_\ell} \right)' \left( \hat{f}_n - n^{-1}\sum_{\ell=1}^n E_{f_\ell} \right) \left( \hat{f}_n - n^{-1}\sum_{\ell=1}^n E_{f_\ell} \right)' = n^{-1}\sum_{i=1}^n \left( \begin{array}{c}
Z_iu_i \\
-vec(Z_iV_{2i}' - Z_{ni}')
\end{array} \right) \left( \begin{array}{c}
Z_iu_i \\
-vec(Z_iV_{2i}' - Z_{ni}')
\end{array} \right)' + o_p(1)
\]

\[
= n^{-1}\sum_{i=1}^n \left( \begin{array}{c}
u_i \\
-V_{2i}
\end{array} \right) \left( \begin{array}{c}
u_i \\
-V_{2i}
\end{array} \right)' \otimes Z_iZ_i' \left( \begin{array}{c}
0^{k \times k} \\
0^{k \times kp} \\
0^{kp \times k}
\end{array} \right) + n^{-1}\sum_{i=1}^n \left( \begin{array}{c}
0^k \\
-Z_{ni}'
\end{array} \right) \left( \begin{array}{c}
Z_iu_i \\
-vec(Z_iV_{2i}')
\end{array} \right)' + o_p(1)
\]

\[
= \left( \begin{array}{c}
1 - \theta_0' \\
0^p - I_p
\end{array} \right) \Sigma_V \left( \begin{array}{c}
1 - \theta_0' \\
0^p - I_p
\end{array} \right)' \otimes \left( n^{-1}\sum_{i=1}^n Z_iZ_i' \right) + \left( \begin{array}{c}
0^{k \times k} \\
0^{k \times kp} \\
0^{kp \times k}
\end{array} \right) \zeta(\pi_n) + o_p(1)
\]

\[
= (B'\Sigma_V B) \otimes \left( n^{-1}\sum_{i=1}^n Z_iZ_i' \right) + \left( \begin{array}{c}
0^{k \times k} \\
0^{k \times kp} \\
0^{kp \times k}
\end{array} \right) \zeta(\pi_n) + o_p(1),
\]

where the second equality holds using \( Eu_i = 0, EV_{2i} = 0^p, Y_{2i} = \pi_n'Z_i + V_{2i}, vec(Z_iV_{2i}') = vec(Z_iV_{2i}') + Z_{ni}' \), and Lemma 29.2(a) and (e) because \( \hat{f}_n - n^{-1}\sum_{\ell=1}^n E_{f_\ell} \to (\mathcal{G}_n, vec(\mathcal{G}_n - n^{-1}\sum_{\ell=1}^n EG_{\ell}'))' \), the third equality holds by (29.26) and simple rearrangement, the fourth equality holds because (i) the first summand on the rhs of the fourth equality is the mean of the first
summand on the lhs of the fourth equality using \( u_i = (1, -\theta_i^0) V_i \), (ii) the variance of each element of the lhs matrix is \( o(1) \) because \( E[|V_i|^4] < \infty \) and \( n^{-1} \sum_{i=1}^n |Z_i|^4 = o(n) \) by Assumption HLIV(b)-(c) (because \( n^{-1} \sum_{i=1}^n |Z_i|^4 \leq n^{-1} \sum_{i=1}^n |Z_i|^2 \cdot \mathbb{1}(|Z_i| > 1) + 1 \leq n^{-1} \sum_{i=1}^n |Z_i|^6 + 1 = o(n) \) using Assumption HLIV(c)), (iii) \( \zeta_n(\pi_n) \rightarrow \zeta(\pi_\ast) \) by Assumption HLIV2(a)-(b), and (iv) the third and fourth summands on the lhs of the fourth equality have zero means and the variance of each element of these summands is \( o(1) \) (because each variance is bounded by \( n^{-2} \sum_{i=1}^n |Z_{ni}^\ast|^2 |Z_i|^2 \leq ||\pi_n||^2 (n^{-2} \sum_{i=1}^n |Z_i|^2 + 2n^{-2} \sum_{i=1}^n |Z_i|^4 n^{-1} \sum_{i=1}^n |Z_i|^2 + n^{-2} \sum_{i=1}^n |Z_i|^2 (n^{-1} \sum_{i=1}^n |Z_i|^2)^2) = o(1) \), using \( ||Z_{ni}^\ast|| \leq ||\pi_n|| (||Z_i||^2 + n^{-1} \sum_{i=1}^n |Z_i|^2) \), \( \sup_{\pi \in \Pi} ||\pi_n|| < \infty \), and \( E[|V_i|^2] < \infty \) by Assumption HLIV(b)-(d)), and the fifth equality holds by the definition of \( B \) in (5.3).

Using the definitions of \( \tilde{R}_n \) in (5.3) and \( R(\pi_\ast) \) in (19.7), part (a) of the lemma follows from (29.27).

Next we prove part (b). We have

\[
\tilde{\Sigma}_{j\ell n} = tr(\tilde{R}_{j\ell n}^\ast \tilde{\Omega}_n^{-1})/k \rightarrow_p tr(R_{j\ell}(\pi_\ast) ((b_0^0 \Sigma_V b_0)^{-1} K_Z^{-1})) / k =: (b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V^\ast j\ell},
\]

(29.28)

where \( \tilde{\Sigma}_{j\ell n} \) and \( \Sigma_{V^\ast j\ell} \) denote the \((j, \ell)\) elements of \( \tilde{\Sigma}_n \) and \( \Sigma_{V^\ast} \), respectively, \( \tilde{R}_{j\ell n}^\ast \) and \( R_{j\ell}(\pi_\ast) \) denote the \((j, \ell)\) submatrices of dimension \( k \times k \) of \( \tilde{R}_n \) and \( R(\pi_\ast) \), respectively, the convergence holds by part (a) of the lemma and Lemma 19.1(b), and the last equality holds by the definition of \( \Sigma_{V^\ast j\ell} \) in (19.8). Equation (29.28) establishes part (b).

Part (c) holds because part (b) of the lemma and Lemma 22.1(e) imply that \( \tilde{\Sigma}_n^\varepsilon \rightarrow_p ((b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V^\ast}^\varepsilon) \), Lemma 22.1(d) implies that \( ((b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V^\ast}^\varepsilon) = (b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V^\ast}^\varepsilon \), and Assumption HLIV2(c) implies that \( \Sigma_{V^\ast}^\varepsilon = \Sigma_{V^\ast} \).

To prove part (d), we have

\[
n^{1/2} \hat{D}_n^\varepsilon := n^{1/2} \tilde{\Omega}_n^{-1/2} \tilde{D}_n \tilde{L}_n^{1/2}
\]

\[
= ((b_0^0 \Sigma_V b_0 K_Z)^{-1/2} K_Z^{-1/2} + o_p(1)) (n^{-1} Z_{n\times k}^\varepsilon Z_{n\times k}^\varepsilon)^{-1/2} n^{1/2} (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0^0 L_{V_0}^{1/2}
\]

\[
\times (L_{V_0}^{1/2} (b_0^0 \Sigma_V b_0 L_{V^\ast})^{-1/2} + o_p(1)) + o_p(1)
\]

\[
= -(I_k + o_p(1)) (n^{-1} Z_{n\times k}^\varepsilon Z_{n\times k}^\varepsilon)^{-1/2} n^{1/2} (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0 L_{V_0}^{-1/2} (L_{V_0}^{1/2} L_{V^\ast}^{1/2} + o_p(1)) + o_p(1)
\]

\[
= -(I_k + o_p(1)) \tilde{F}_n (L_{V_0}^{1/2} L_{V^\ast}^{1/2} + o_p(1)) + o_p(1),
\]

(29.29)

where the first equality holds by the definition of \( \hat{D}_n^\varepsilon \) in (5.7), the second equality holds by (i) (29.14), (ii) the result of part (c) of the lemma that \( \tilde{\Sigma}_n^\varepsilon \rightarrow_p ((b_0^0 \Sigma_V b_0)^{-1} \Sigma_{V^\ast}^\varepsilon) \), (iii) the result of Lemma 19.1(b) that \( \tilde{\Omega}_n \rightarrow_p (b_0^0 \Sigma_V b_0) K_Z \), (iv) \( n^{-1} Z_{n\times k}^\varepsilon Z_{n\times k}^\varepsilon \rightarrow K_Z \) by Assumption HLIV(c), (v)
Lemma 19.3. Proof of Lemma 19.3

Lemma 19.3 Suppose Assumption HLIV holds and \( p = 1 \). Under the null hypothesis \( H_0 : \theta = \theta_0 \), for any sequence of reduced-form parameters \( \{ \pi_n \in \Pi : n \geq 1 \} \), we have: (a) \( r k_1(\theta_0) = T_n^0[I_k + L V_0 K_{Z}^{-1/2} \zeta(\pi_n) K_{Z}^{-1/2} + o_p(1)]^{-1} T_n \cdot (1 + o_p(1)) + o_p(1) \), (b) \( r k_2(\theta_0) = T_n^0 T_n (L V_0 b'_0 \Sigma V b_0)^{-1} \cdot (1 + o_p(1)) + o_p(1) \), where \( L V_0 := (\theta_0, 1) \Sigma_V^{-1}(\theta_0, 1)' \in R \), and (c) \( L V_0 b'_0 \Sigma V b_0 = \frac{(1-2 \theta_0 \rho + \theta_0^2 \sigma_2^2)}{c^2(1-\rho^2)} \), where \( \rho = Corr(V_{1i}, V_{2i}) \in (-1, 1) \).

When \( p = 1 \), we write

\[
\Sigma_V := EV_i V_i' := (\Sigma_{V1}, \Sigma_{V2}) := \begin{pmatrix} \sigma_1^2 & \rho \sigma_1 \sigma_2 \\ \rho \sigma_1 \sigma_2 & \sigma_2^2 \end{pmatrix} \in R^{2 \times 2}
\]

(29.30)

for \( \Sigma_{V1}, \Sigma_{V2} \in R^{2} \), using the definition in (19.2).

The proof of Lemma 19.3 uses the following lemma.

Lemma 29.3 Under the conditions of Lemma 19.3, (a) \( L V_0 = \frac{\sigma_1^2 - 2 \theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2}{\sigma_1^2 \sigma_2^2 (1-\rho^2)} > 0 \), (b) \( b'_0 \Sigma V b_0 = \sigma_1^2 - 2 \theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2 \), and (c) \( L V_0 (\sigma_2^2 - (b'_0 \Sigma V b_0)^2 (b'_0 \Sigma V b_0)^{-1}) = 1 \).

Proof of Lemma 19.3 We prove part (b) first. By (29.9) and (29.14),

\[
n^{1/2} \tilde{\Omega}_n^{-1/2} \tilde{D}_n = n^{1/2} (I_k + o_p(1)) (n^{-1} Z_n' Z_n)^{-1/2} (\hat{g}_n, \hat{G}_n) B \Sigma_V^{-1} A_0 (b'_0 \Sigma V b_0)^{-1/2} + o_p(1)
\]

\[
= -n^{1/2} (I_k + o_p(1)) (n^{-1} Z_n' Z_n)^{-1/2} (\hat{g}_n, \hat{G}_n) B \Sigma_V^{-1} A_0 L V_0^{-1} (b'_0 \Sigma V b_0)^{-1/2} + o_p(1)
\]

\[
= -(I_k + o_p(1)) T_n (L V_0 b'_0 \Sigma V b_0)^{-1/2} + o_p(1),
\]

(29.31)

where the second equality holds by Lemma 29.1 and the third equality holds by (29.12). Because \( T_n' (I_k + o_p(1)) T_n = T_n' T_n + o_p(1) || T_n' ||^2 \), the result of part (b) follows.

116
Next, we prove part (a). We have

\[
    n^{-1} \sum_{i=1}^{n} (G_i - \hat{G}_n)(G_i - \hat{G}_n)'
    = n^{-1} \sum_{i=1}^{n} \left( G_i - n^{-1} \sum_{\ell=1}^{n} E G_{\ell} \right) \left( G_i - n^{-1} \sum_{\ell=1}^{n} E G_{\ell} \right)' - \left( \hat{G}_n - n^{-1} \sum_{i=1}^{n} E G_i \right) \left( \hat{G}_n - n^{-1} \sum_{i=1}^{n} E G_i \right)'
    = n^{-1} \sum_{i=1}^{n} \left( -Z_i Z_i' \pi_n - Z_i V_{2i} + n^{-1} \sum_{\ell=1}^{n} Z_{\ell} Z_{\ell}' \pi_n \right) \left( -Z_i Z_i' \pi_n - Z_i V_{2i} + n^{-1} \sum_{\ell=1}^{n} Z_{\ell} Z_{\ell}' \pi_n \right)' + o_p(1)
    = n^{-1} \sum_{i=1}^{n} (Z_i V_{2i})(Z_i V_{2i})' + 2n^{-1} \sum_{i=1}^{n} (Z_i Z_i' \pi_n)(Z_i V_{2i})' - 2 \left( n^{-1} \sum_{\ell=1}^{n} Z_{\ell} Z_{\ell}' \pi_n \right) \left( n^{-1} \sum_{\ell=1}^{n} Z_{\ell} V_{2i} \right)'
    + \zeta_n(\pi_n) + o_p(1)
    = n^{-1} Z_{n \times k}' Z_{n \times k} \sigma_2^2 + \zeta_n(\pi_n) + o_p(1),
\]

(29.32)

where the first equality holds by algebra, the second equality holds by Lemma 29.2(e), \( G_i = -Z_i Y_{2i} \), \( Y_{2i} = Z_i' \pi_n + V_{2i} \), and so \( Y_{2i} - E Y_{2i} = V_{2i} \), the third equality holds by multiplying out the terms on the lhs of the third equality and using the definition of \( \zeta_n(\pi) \) in (19.15), the first summation on the rhs of the fourth equality equals the first summation on the rhs of the fourth equality plus \( o_p(1) \) by the same argument as for Lemma 29.2(d) with \( V_{2i}^2 \) in place of \( u_i^2 \) and \( \sigma_2^2 := E V_{2i}^2 \) in place of \( Eu_i^2 \), the second summation on the rhs of the fourth equality is \( o_p(1) \) because it has mean zero and its elements have variances that are bounded by \( 4 \sigma_2^2 n^{-2} \sum_{i=1}^{n} ||Z_i||^6 \sup_{\pi \in \Pi} ||\pi||^2 \), which is \( o(1) \) by Assumption HLIV(c)-(d), and the third summation on the rhs of the fourth equality is \( o_p(1) \) because \( n^{-1} \sum_{\ell=1}^{n} Z_i Z_i' \pi_n = O(1) \) by Assumption HLIV(c) and (d) and \( n^{-1} \sum_{\ell=1}^{n} Z_i V_{2i} = o_p(1) \) by the argument following (29.23).

Combining (29.9), (29.13), (29.32) and the definition of \( \tilde{V}_{Dn} \) in (19.14), we obtain

\[
    \tilde{V}_{Dn} = n^{-1} \sum_{i=1}^{n} Z_i Z_i' (\sigma_2^2 - (b_0' \Sigma V_2)^2 (b_0' \Sigma V_2^{-1} b_0) b_0' \Sigma V_2^{-1} A_0 L_{V_0}^{-1} b_0) + \zeta_n(\pi_n) + o_p(1)
    = K_Z L_{V_0}^{-1} + \zeta_n(\pi_n) + o_p(1),
\]

(29.33)

where the second equality holds by Lemma 29.3(c) and Assumption HLIV(c).

Next, we have

\[
    n^{1/2} \left( n^{-1} Z_{n \times k}' Z_{n \times k} \right)^{-1/2} \tilde{D}_n L_{V_0}^{-1/2} = n^{1/2} \left( n^{-1} Z_{n \times k}' Z_{n \times k} \right)^{-1/2} (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0 L_{V_0}^{-1/2} + o_p(1)
    = -n^{1/2} \left( n^{-1} Z_{n \times k}' Z_{n \times k} \right)^{-1/2} (\tilde{g}_n, \tilde{G}_n) B \Sigma_V^{-1} A_0 L_{V_0}^{-1/2} + o_p(1) = -\tilde{T}_n + o_p(1),
\]

(29.34)

where the first equality holds by (29.14), the second equality holds by Lemma 29.1 and the third
equality holds by \((29.12)\).

Using \((29.33)\), we obtain

\[
n^{1/2} \hat{V}_{D_n}^{-1/2} \hat{D}_n = [K_Z L_{V_0}^{-1} + \zeta_n(\pi_n) + o_p(1)]^{-1/2} n^{1/2} \hat{D}_n
\]

\[
= -[K_Z L_{V_0}^{-1} + \zeta_n(\pi_n) + o_p(1)]^{-1/2} (n^{-1} Z_{n \times k} Z_{n \times k})^{1/2} \hat{T}_n L_{V_0}^{-1/2} + o_p(1)
\]

\[
= -[K_Z L_{V_0}^{-1} + \zeta_n(\pi_n) + o_p(1)]^{-1/2} K_Z^{1/2} \hat{T}_n L_{V_0}^{-1/2} (1 + o_p(1)) + o_p(1),
\]

where the second equality holds using \((29.34)\) and Assumption HLIV(c), the third equality holds by Assumption HLIV(c) and some calculations. Using this, we obtain

\[
rk_{1n} := n \hat{D}_n^{-1} \hat{V}_{D_n}^{-1} \hat{D}_n = T_n K_Z^{1/2} [K_Z L_{V_0}^{-1} + \zeta_n(\pi_n) + o_p(1)]^{-1} K_Z^{1/2} \hat{T}_n L_{V_0}^{-1} (1 + o_p(1)) + o_p(1)
\]

\[
= \hat{T}_n [I_k + L_{V_0} K_Z^{1/2} \zeta_n(\pi_n) K_Z^{1/2} + o_p(1)]^{-1} \hat{T}_n (1 + o_p(1)) + o_p(1),
\]

where the last equality holds by some algebra. This proves part (a) of the lemma.

Part (c) of the lemma follows from Lemma 29.3(a) and (b) by substituting in \(\sigma_2^2 = c^2 \sigma_1^2\). \(\square\)

**Proof of Lemma 29.3** Part (a) holds by the following calculations:

\[
L_{V_0} := (\theta_0, 1) \begin{pmatrix} \sigma_1^2 & \rho \sigma_1 \sigma_2 \\ \rho \sigma_1 \sigma_2 & \sigma_2^2 \end{pmatrix}^{-1} \begin{pmatrix} \theta_0 \\ 1 \end{pmatrix}
\]

\[
= \frac{1}{\sigma_1^2 \sigma_2^2(1 - \rho^2)} (\theta_0, 1) \begin{pmatrix} \sigma_2^2 & -\rho \sigma_1 \sigma_2 \\ -\rho \sigma_1 \sigma_2 & \sigma_1^2 \end{pmatrix} \begin{pmatrix} \theta_0 \\ 1 \end{pmatrix} = \frac{\sigma_1^2 - 2\theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2}{\sigma_1^2 \sigma_2^2(1 - \rho^2)}.
\]

We have \(L_{V_0} > 0\) because \(\Sigma_V\) is pd by Assumption HLIV(b) and \((\theta_0, 1) \neq 0_2\).

Part (b) holds by the first of the following two calculations:

\[
b_0' \Sigma_V b_0 := (1, -\theta_0) \begin{pmatrix} \sigma_1^2 & \rho \sigma_1 \sigma_2 \\ \rho \sigma_1 \sigma_2 & \sigma_2^2 \end{pmatrix} \begin{pmatrix} 1 \\ -\theta_0 \end{pmatrix} = \sigma_1^2 - 2\theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2 \text{ and}
\]

\[
b_0' \Sigma_{V_2} := (1, -\theta_0)(\rho \sigma_1 \sigma_2, \sigma_2^2)' = \rho \sigma_1 \sigma_2 - \theta_0 \sigma_2^2.
\]

Using \((29.38)\), we obtain

\[
\sigma_2^2 - (b_0' \Sigma_{V_2})^2 (b_0' \Sigma_V b_0)^{-1} = \sigma_2^2 - \frac{(\rho \sigma_1 \sigma_2 - \theta_0 \sigma_2^2)^2}{\sigma_1^2 - 2\theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2}
\]

\[
= \frac{\sigma_2^2 \sigma_1^2 - 2\theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2 - (\rho \sigma_1 \sigma_2 - \theta_0 \sigma_2^2)^2}{\sigma_1^2 - 2\theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2} = \frac{\sigma_2^2 \sigma_1^2(1 - \rho^2)}{\sigma_1^2 - 2\theta_0 \rho \sigma_1 \sigma_2 + \theta_0^2 \sigma_2^2} = L_{V_0}^{-1}.
\]

118
which proves part (c). □

30 Proof of Theorem 18.1

In Sections 16 and 17 we establish Theorems 6.1 and 15.2 by first establishing Theorem 16.1 which concerns non-SR versions of the AR, CQLR, and CQLRₚ tests and employs the parameter spaces \( \mathcal{F}_{AR}, \mathcal{F}, \) and \( \mathcal{F}_P \) , rather than \( \mathcal{F}_{AR}^{SR}, \mathcal{F}^{SR}, \) and \( \mathcal{F}_P^{SR} \). We prove Theorem 18.1 here using the same two-step approach.

In the time series context, the non-SR version of the AR statistic is defined as in (4.2) based on \( \{ f_i - \hat{f}_n : i \leq n \} \), but with \( \hat{\Omega}_n \) defined in (18.3) and Assumption \( \Omega \) below, rather than in (4.1), and the critical value is \( \chi^2_{k, 1-\alpha} \). The non-SR QLR time series test statistic and conditional critical value are defined as in Section 5.1, but with \( \hat{V}_n \) and \( \hat{\Omega}_n \) defined in (18.3) and Assumption V below based on \( \{ f_i - \hat{f}_n : i \leq n \} \), in place of \( \hat{V}_n \) and \( \hat{\Omega}_n \) defined in (5.3) and (4.1), respectively. The non-SR QLRₚ time series test statistic and conditional critical value are defined as in Section 15 but with \( \hat{V}_n \) and \( \hat{\Omega}_n \) defined in (18.3) and Assumption \( V_P \) below based on \( \{ (u_i^* - \hat{u}_m^*) \otimes Z_i : i \leq n \} \), rather than in (15.5) and (4.1), respectively.

For the (non-SR) AR, (non-SR) CQLR and (non-SR) CQLRₚ tests in the time series context, we use the following parameter spaces. We define

\[
\mathcal{F}_{TS,AR} := \{ F : \{ W_i : i = \ldots, 0, 1, \ldots \} \text{ are stationary and strong mixing under } F \text{ with } \text{ strong mixing numbers } \{ \alpha_F(m) : m \geq 1 \} \text{ that satisfy } \alpha_F(m) \leq Cm^{-d}, \quad E_F g_i = 0^k, \quad E_F ||g_i||^{2+\gamma} \leq M, \quad \text{and } \lambda_{\min}(\Omega_F) \geq \delta \}
\]

for some \( \gamma, \delta > 0, \), \( d > (2 + \gamma)/\gamma, \) and \( C, M < \infty, \) where \( \Omega_F \) is defined in (18.4). We define \( \mathcal{F}_{TS} \) and \( \mathcal{F}_{TS,P} \) as \( \mathcal{F} \) and \( \mathcal{F}_P \) are defined in (16.1), respectively, but with \( \mathcal{F}_{TS,AR} \) in place of \( \mathcal{F}_{AR} \). For CS’s, we use the corresponding parameter spaces \( \mathcal{F}_{TS,\Theta,AR} := \{ (F, \theta_0) : F \in \mathcal{F}_{TS,AR}(\theta_0), \theta_0 \in \Theta \}, \mathcal{F}_{TS,\Theta} := \{ (F, \theta_0) : F \in \mathcal{F}_{TS}(\theta_0), \theta_0 \in \Theta \}, \text{ and } \mathcal{F}_{TS,\Theta,P} := \{ (F, \theta_0) : F \in \mathcal{F}_{TS,P}(\theta_0), \theta_0 \in \Theta \}, \) where \( \mathcal{F}_{TS,AR}(\theta_0), \mathcal{F}_{TS}(\theta_0), \) and \( \mathcal{F}_{TS,P}(\theta_0) \) denote \( \mathcal{F}_{TS,AR}, \mathcal{F}_{TS}, \) and \( \mathcal{F}_{TS,P}, \) respectively, with their dependence on \( \theta_0 \) made explicit.

For the (non-SR) CQLR test and CS in the time series context, we use the following assumptions.

**Assumption V:** \( \hat{V}_n(\theta_0) - V_{F_n}(\theta_0) \to_p 0^{(p+1)k \times (p+1)k} \) under \( \{ F_n : n \geq 1 \} \) for any sequence \( \{ F_n \in \mathcal{F}_{TS,P} : n \geq 1 \} \) for which \( V_{F_n}(\theta_0) \to V \) for some matrix \( V \) whose upper left \( k \times k \) submatrix \( \Omega \) is pd.

**Assumption V-CS:** \( \hat{V}_n(\theta_{0n}) - V_{F_n}(\theta_{0n}) \to_p 0^{(p+1)k \times (p+1)k} \) under \( \{ (F_n, \theta_{0n}) : n \geq 1 \} \) for any
For each test. Then, these tests have asymptotic sizes equal to their nominal size $\alpha \in (0,1)$ and are asymptotically similar (in a uniform sense).

Analogous results hold for the AR, CQLR, and CQLR$_P$ tests for the parameter spaces $F_{TS,AR}$, $F_{TS}$, and $F_{TS,P}$, respectively, provided the corresponding Assumption $\Omega$-CS, $V$-CS, or $V_P$ holds for each CS, rather than Assumption $\Omega$, $V$, or $V_P$.

The proof of Theorem [18.1] uses Theorem [30.1] and the following lemma.

**Lemma 30.2** Suppose $\{X_i : i = \ldots, 0, 1, \ldots\}$ is a strictly stationary sequence of mean zero, square integrable, strong mixing random variables. Then, $\text{Var}(\bar{X}_n) = 0$ for any $n \geq 1$ implies that $X_i = 0$ a.s., where $\bar{X}_n := \frac{1}{n} \sum_{i=1}^{n} X_i$.

**Proof of Theorem [18.1]** The proof of Theorem [18.1] using Theorem [30.1] is essentially the same as the proof (given in Section [17]) of Theorems 6.1 and 15.2 using Theorem [16.1] and Lemma [17.1].

Thus, we need an analogue of Lemma [17.1] to hold in the time series case. The proof of Lemma [17.1] (given in Section [17]) goes through in the time series case, except for the following:

(i) in the proof of $\hat{\tau} \leq r$ (as $r F_n$) a.s. $\forall n \geq 1$ we replace the statement “for any constant vector $\lambda \in R^k$ for which $\lambda' \Omega F_n \lambda = 0$, we have $\lambda' g_i = 0$ a.s.$[F_n]$ and $\lambda' \tilde{\Omega} n \lambda = n^{-1} \sum_{i=1}^{n} (\lambda' g_i)^2 - (\lambda' g_n)^2 = 0$ a.s.$[F_n]$” by the statement “for any constant vector $\lambda \in R^k$ for which $\lambda' \Omega F_n \lambda = 0$, we have $\lambda' g_i = 0$ a.s.$[F_n]$ by Lemma [30.2] (with $X_i = \lambda' g_i$) and in consequence $\lambda' \tilde{\Omega} n \lambda = 0$ a.s.$[F_n]$ by Assumption SR-V(c), SR-V-CS(c), SR-V$_P$(c), SR-V$_P$-CS(c), SR-\Omega(c), or SR-\Omega-CS(c).”

120
Proof of Theorem 30.1. The proof is essentially the same as the proof of Theorem 16.1 (given in Section 27) and the proofs of Lemma 16.4 and Proposition 16.5 (given in Section 25 above and Section 17 in the SM of AG1, respectively) for the i.i.d. case, but with some modifications. The modifications are the first, second, third, and fifth modifications stated in the proof of Theorem 7.1 in AG1, which is given in Section 20 in the SM to AG1. Briefly, these modifications involve: (i) the definition of $\lambda_{5,F}$, (ii) justifying the convergence in probability of $\widehat{F}_n$ and the positive definiteness of its limit by Assumption V, V-CS, V $P$, or V $P$-CS, rather than by the WLLN for i.i.d. random variables, (iii) justifying the convergence in probability of $\hat{b}_n$ by Assumption V, V-CS, V $P$, or V $P$-CS, rather than by the WLLN for i.i.d. random variables, and (iv) using the WLLN and CLT for triangular arrays of strong mixing random vectors given in Lemma 20.1 in the SM of AG1, rather than the WLLN and CLT for i.i.d. random vectors. For more details on the modifications, see Section 20 in the SM to AG1. These modifications affect the proof of Lemma 16.4. No modifications are needed elsewhere. □

Proof of Lemma 30.2. Suppose $\text{Var}(X_n) = 0$. Then, $X_n$ equals a constant a.s. Because $E X_n = 0$, the constant equals zero. Thus, $\sum_{i=1}^{n} X_i = 0$ a.s. By strict stationarity, $\sum_{i=1}^{n} X_{i+sn} = 0$ a.s. and $\sum_{i=2}^{n+1} X_{i+sn} = 0$ a.s. for all integers $s \geq 0$. Taking differences yields $X_{1+sn} = X_{1+n+sn}$ for all $s \geq 0$. That is, $X_1 = X_{1+sn}$ for all $s \geq 1$.

Let $A$ be any Borel set in $R$. By the strong mixing property, we have

$$
\xi_s := |P(X_1 \in A, X_{1+sn} \in A) - P(X_1 \in A)P(X_{1+sn} \in A)| \leq \alpha_X(sn) \to 0 \text{ as } s \to \infty, \quad (30.2)
$$

where $\alpha_X(m)$ denotes the strong mixing number of $\{X_i : i = \ldots, 0, 1, \ldots\}$ for time period separations of size $m \geq 1$. We have

$$
\xi_s = |P(X_1 \in A) - P(X_1 \in A)^2| = P(X_1 \in A)(1 - P(X_1 \in A)), \quad (30.3)
$$
where the first equality holds because $X_1 = X_{1+n}$ a.s. and by strict stationarity. Because $\xi_s \to 0$ as $s \to \infty$ by (30.2) and $\xi_s$ does not depend on $s$ by (30.3), we have $\xi_s = 0$. That is, $P(X_1 \in A)$ equals zero or one (using (30.3)) for all Borel sets $A$ and, hence, $X_i$ equals a constant a.s. Because $EX_i = 0$, the constant equals zero. □

31 Proof of Theorems 9.1, 13.1, and 9.2

31.1 Proof of Theorem 9.1

To prove Theorem 9.1, we use the same proof structure as for the full vector test. Like the proof for the full vector test, the proof of Theorem 9.1 is based on a number of intermediate lemmas, propositions, and theorems. A key change is that the role of $E_F G_i \in R^{k\times p}$ in the full vector case is played by $O_F^1(E_F g_i g_i')^{-1/2}E_F G_i \in R^{(k-b)\times p}$ in the subvector case, where $O_F \in R^{k\times (k-b)}$, defined below, is such that $M_{(E_F g_i g_i')^{-1/2}E_F G_i^b} = O_F O_F^1$. In this sense, the role of $k$ is replaced by $k-b$.

The proof of the full vector case is given for a general CQLR test that employs weighting matrices $\widehat{W}_n$ and $\widehat{U}_n$ that satisfy a certain high level condition Assumption WU. In particular, $\widehat{W}_n$ and $\widehat{U}_n$ converge to certain matrices $W_{F_n}$ and $U_{F_n}$, respectively. We follow that structure and prove the result of the theorem for a general CQLR test. However, for the subvector test, the weighting matrices $\widehat{W}_n$ and $W_{F_n}$ are set equal to the identity matrix and therefore do not appear in the high level Assumption $WU^S$, which adapts Assumption WU from the full vector test. We verify Assumption $WU^S$ for the specific choice of weighting matrix $\widehat{U}_n$ employed in the subvector CQLR test (9.11), which is $\widehat{U}_n = \widehat{U}_n^{1/2}(\theta_0, \widehat{\beta}_n)$, in Lemma 31.9 below.

A general QLR_{WU} subvector test statistic is defined as

\[ QLR_{WU,n}^S := a P_n^S(\theta_0, \widehat{\beta}_n) - \lambda_{\min}(n Q_{WU,n}^S), \]  
\[ \hat{Q}_{WU,n}^S := (\Omega_n^{-1/2}(\widehat{\eta}) \bar{D}_n(\widehat{\eta}) \hat{U}_n, \Omega_n^{-1/2}(\widehat{\eta}) \bar{D}_n(\widehat{\eta}) \hat{U}_n, \Omega_n^{-1/2}(\widehat{\eta}) \bar{D}_n(\widehat{\eta}) \hat{U}_n) \] 

for $\widehat{\eta} := (\hat{\theta}_0, \hat{\beta}_n)'$, and $\hat{U}_n := U_1(\widehat{U}_2n)$ is defined as in (16.4). Here, we keep the $WU$ notation from the full vector test, even though no $W$-type matrix affects the statistic. The population counterpart $U_F := U_1(U_{2F})$ of $\hat{U}_n$ is defined as in (16.5). The general QLR_{WU} test rejects the null hypothesis if

\[ QLR_{WU,n}^S > c_{k,p}(D, J, 1 - \alpha), \]  

where $c_{k,p}(D, J, 1 - \alpha)$ is defined in (9.12).\(^{70}\)

\(^{70}\)The reason $\Omega_n^{-1/2}$ is used in the definitions of $QLR_n^S(\theta, \widehat{\beta}_n)$ in (9.11) and $QLR_{WU,n}^S$, rather than $\Omega_n^{-1/2}$, is that...
The proof for the subvector test result is based on working out the asymptotic null rejection probabilities along certain drifting sequences of parameters \( \{ \lambda_{n,h} : n \geq 1 \} \) that we introduce below \((31.15)\). The notation involving \( \lambda \) and \( h \) in \((16.16)\) and \((16.19)\) for the full vector case has to be adapted to the subvector case. The argument \( \theta_0 \) in the notation for expressions for full vector inference is replaced throughout by the argument \((\theta_0, \beta^*)\). For example, in \( \lambda_{n,F}^S = E_F G_i, G_i \) abbreviates \( G_i(\theta_0, \beta^*) \), rather than \( G_i(\theta_0) \) as in the full vector case. In addition, relative to \( \lambda_{n,h} \) for the full vector case, \( \lambda_{n,h}^S \) contains several additional components, such as \( \lambda_{4,bj\beta,F}^S := E_F G_i b_j \beta \) for \( j = 1, ..., p \) and \( \lambda_{4,bj\beta,F}^S := E_F G_i b_j \beta \) for \( j = 1, ..., b \).

Construction of bases \( O_{F_n} \) and \( \hat{O}_{F_n} \) for the spaces spanned by the eigenvectors corresponding to the eigenvalue 1 of two projection matrices. For a projection matrix, the eigenvalues are 0 or 1. When deriving the asymptotic distribution of \( \hat{Q}_n(\theta_0, \beta_n) \) in \((9.11)\), which is part of the test statistic \( QLR_n^S(\theta_0, \beta_n) \), it is helpful to factor \( M_{f_n(\eta)} \) into a product \( \hat{O}_n \hat{O}_n^T \) where \( \hat{O}_n \in R^{k \times (k-b)} \) contains a basis for the space of eigenvectors spanned by the eigenvalue 1 of the projection matrix \( M_{f_n(\eta)} \). Given this factorization, we consider the quantities \( (\hat{O}_n^{-1/2(\eta) \hat{g}}_n(\eta), \hat{O}_n^{T} \hat{D}_n^*(\eta)) \), which puts us into the framework used in the proof for the full vector test. Note that, in general, eigenvectors are not continuous functions of a matrix. However, in the case of a projection matrix, the eigenvalues are well separated and eigenvectors that are continuous can be explicitly constructed.

We now outline this construction. First, given a sequence of nonstochastic matrices \( \{ J_n \in R^{k \times b} : n \geq 1 \} \) that satisfy \( J_n \rightarrow J \) with \( J \) of full column rank \( b \), we construct matrices \( O_n \) and \( O \in R^{k \times (k-b)} \) such that \( M_{f_n} = O_n O_n^T, M_J = O O', \) and \( O_n \rightarrow O \). To do so, note first that for any \( O' \in R^{(k-b) \times k} \) having rows that contain an orthonormal basis of eigenvectors of the eigenvalue 1, we have \( M_J = O O' \). A basis of eigenvectors of the eigenvalue 0 is given by the columns of \( J \). Therefore, the space of eigenvectors corresponding to the eigenvalue 1 is given by \( span(J) \), the orthogonal complement of \( span(J) \). We have \( span(J)^\perp = N(J') \).

There are \( T := \binom{k}{b} \) different sets of \( b \) rows from the set of \( k \) rows of \( J \in R^{k \times b} \). Given that \( J \) has full column rank, there is at least one choice of \( b \) rows of \( J \) that form a basis of \( R^b \). For notational simplicity, assume that the first \( b \) columns of \( J' \) form a basis of \( R^b \) \( \Box \) Decompose \( J' = (J'_1, J'_2) \) with

we prove the subvector results using the proof of the full vector result with \( \hat{W}_n, W_{F_n} \), and \( \hat{D}_n \in R^{k \times p} \) replaced by \( I_b, I_b, \) and \( \hat{O}_n^{-1/2(\eta) \hat{g}}_n(\eta) \hat{D}_n(\theta_0, \beta_n) \in R^{(k-b) \times p} \), respectively, where \( \hat{O}_n \in R^{(k-b) \times k} \), defined below, is such that \( \hat{O}_n \hat{O}_n^T = M_{f_n(\theta_0, \beta_n)} \). For the full vector results, the difference between \( \hat{W}_n \) and \( W_{F_n} \) can be handled easily because \( \hat{W}_n W_{F_n}^{-1} \rightarrow I_p \) (as in \((26.8)\)). But, in the subvector case, the same strategy cannot be applied to \( \hat{O}_n^{-1/2(\eta) \hat{g}}_n(\theta_0, \beta_n) \) and \((E_{F_n}, g, g)\)^{-1/2}, because of the factor \( \hat{O}_n \), that precedes \( \hat{O}_n^{-1/2(\eta) \hat{g}}_n(\theta_0, \beta_n) \) in the definition of \( \hat{O}_n \hat{D}_n(\theta_0, \beta_n) \), which is the subvector equivalent to \( D_n \).
\( J'_1 \in R^{b\times b} \) and \( J'_2 = (j_1, \ldots, j_{k-b}) \in R^{b \times (k-b)} \), \( j_s \in R^b \) for \( s = 1, \ldots, k - b \). It follows that a basis of \( N(J') \) is given by the vectors \((-j'_s J^{-1}_1, e'_s)^t \in R^k\) for \( s = 1, \ldots, k - b \), where \( e_s \) denotes the \( s \)-th coordinate vector in \( R^{k-b} \). This holds because

\[
J' \left( \begin{array}{c}
-J^{-1}_1 j_s \\
\quad e_s
\end{array} \right) = (J'_1, J'_2) \left( \begin{array}{c}
-J^{-1}_1 j_s \\
\quad e_s
\end{array} \right) = 0^b \text{ for } s = 1, \ldots, k - b. \quad (31.3)
\]

Let \( Q' \in R^{(k-b) \times k} \) be a matrix whose \( s \)-th row is given by

\[
(-j'_s J^{-1}_1, e'_s)
\]

for \( s = 1, \ldots, k - b \). Define

\[
O' = O(J)' := (Q'Q)^{-1/2}Q'. \quad (31.5)
\]

The matrix \( OO' \) is symmetric and idempotent and, hence, is a projection matrix. Since the rows of \( Q' \) are orthogonal to the rows of \( J' \), \( OO' \) projects onto the space orthogonal to the columns of \( J \). That is, \( OO' = M_J \). When we want to emphasize which choice of the \( t = 1, \ldots, T \) sets of \( b \) columns from the set of \( k \) columns of \( J' \) is used in the above construction of \( O' = O(J)' \) we add an additional subindex and write

\[
O'_t = O_t(J)' \quad (31.6)
\]

instead.

Use analogous notation for \( J'_n = (J'_{n1}, J'_{n2}), J'_{n1} = (j_{n1}, \ldots, j_{n(k-b)}) \), the matrix \( Q'_n \in R^{(k-b) \times k} \), whose \( s \)-th row is given by \((-j'_{ns} J^{-1}_{n1}, e'_s)\), and \( O'_n = O(J'_n)' := (Q'_n Q_n)^{-1/2}Q'_n \). Then, \( O_n O'_n = M_{J_n} \), \( OO' = M_J \), and \( O'_n \to O' \) as desired, where the convergence follows directly from \( J_n \to J \). Again, when we want to emphasize which set of \( b \) columns of \( J'_n \) is used in the construction, we write

\[
O'_{nt} = O_t(J'_n)' \quad (31.7)
\]

instead.

Under sequences \( \{\lambda^S_{n,h} \in \Lambda^S : n \geq 1\} \) (defined below), this construction is applied to

\[
J_n = (E_{F_n} g_i g_j')^{-1/2} E_{F_n} G_{ij} \quad (31.8)
\]

and the matrix \( O_n \) just constructed also is sometimes denoted by \( O_{F_n} \). Under the sequence \( \{\lambda^S_{n,h} \in \Lambda^S : n \geq 1\} \), it follows that \( J_n \) converges to the matrix \( J_h := (h_{5,5})^{-1/2} h_{4,5} \) defined below.
As in (31.5), for given $F \in \mathcal{F}^S$,

$$O'_F = O'_{Ft} = O((E_F g_i g'_i)^{-1/2} E_F G_{i\beta}^t)'$$  \hspace{1cm} (31.9)$$

denotes a basis of the space of eigenvectors for the eigenvalue 1 for $M((E_F g_i g'_i)^{-1/2} E_F G_{i\beta}^t)$ using the construction outlined above for any choice $t = 1, \ldots, T$ of any $b$ columns of $((E_F g_i g'_i)^{-1/2} E_F G_{i\beta}^t)'$ that form a basis of $R^b$.

Under sequences $\{\lambda_{n,k}^S \in \Lambda^S : n \geq 1\}$, Lemma 31.5 below implies that $\tilde{J}_n(\theta_0, \tilde{\beta}_n) - J_n \in R^{k \times b}$ converges in probability to zero and $J_n = (E_F, g_i g'_i)^{-1/2} E_F G_{i\beta} \rightarrow J_h := (h_{5g})^{-1/2} h_{4,\beta}$. In addition, $J_n$ has full column rank $b$ for all $n$ sufficiently large, under the restrictions in $\mathcal{F}^S$. Therefore, $\tilde{J}_n(\theta_0, \tilde{\beta}_n)$ has full column rank $b$ wp→ 1. For any $b$ columns indexed by $t = 1, \ldots, T$ of $J_h'$ that form a basis of $R^b$ and apply the above construction with this choice of columns to both $\tilde{J}_n(\theta_0, \tilde{\beta}_n)'$ and $J_h'$ to obtain

$$\tilde{O}'_{Ft} = O(\tilde{J}_n(\theta_0, \tilde{\beta}_n))' \in R^{(k-b) \times k} \text{ and } O'_{Ft} = O(J_n)'$$  \hspace{1cm} (31.10)$$

using the notation in (31.5). Given that $\tilde{J}_n(\theta_0, \tilde{\beta}_n) - J_n \rightarrow_p 0^{k \times b}$, it follows that $\tilde{O}'_{Ft} - O'_{Ft} \rightarrow_p 0^{(k-b) \times k}$.

**Definition of $\{\lambda_{n,k}^S \in \Lambda^S : n \geq 1\}$.** As described above, each $t = 1, \ldots, T$ indexes a set of $b$ columns of $((E_F g_i g'_i)^{-1/2} E_F G_{i\beta}^t)'$. For any $t = 1, \ldots, T$ for which the $b$ columns of $((E_F g_i g'_i)^{-1/2} E_F G_{i\beta}^t)'$ form a basis of $R^b$, consider a singular value decomposition of $O'_{Ft}(E_F g_i g'_i)^{-1/2}(E_F G_i)U_F \in R^{(k-b) \times p}$.

More precisely, let $B_F = B_{Ft}$ denote a $p \times p$ orthogonal matrix of eigenvectors of

$$U'_F (E_F G_i)'(E_F g_i g'_i)^{-1/2} O'_{Ft}(E_F g_i g'_i)^{-1/2} E_F G_i U_F$$  \hspace{1cm} (31.11)$$

ordered so that the corresponding eigenvalues $(\kappa_{1Ft}, \ldots, \kappa_{pFt})$ are nonincreasing. Let $C_F = C_{Ft}$ denote a $(k-b) \times (k-b)$ orthogonal matrix of eigenvectors of

$$O'_{Ft}(E_F g_i g'_i)^{-1/2}(E_F G_i)U_F U'_F (E_F G_i)'(E_F g_i g'_i)^{-1/2} O_{Ft}.$$  \hspace{1cm} (31.12)$$

The corresponding eigenvalues are $(\kappa_{1Ft}, \ldots, \kappa_{k-bFt})$.

Let $(\tau_{1Ft}, \ldots, \tau_{\min(k-b,p)Ft})$ denote the min\{ $k-b, p$ \} singular values of

$$O'_{Ft}(E_F g_i g'_i)^{-1/2}(E_F G_i)U_F,$$  \hspace{1cm} (31.13)$$

which are nonnegative and ordered so that $\tau_{jFt}$ is nonincreasing in $j$. For all other $t = 1, \ldots, T$ (for which the $b$ columns of $((E_F g_i g'_i)^{-1/2} E_F G_{i\beta}^t)'$ indexed by $t$ do not form a basis of $R^b$), define
(τ_{1F}, ..., τ_{\min\{k-b,p\}F}) to be a vector of minus ones and \(B_{F1} \) and \(C_{F1} \) to be identity matrices in \(R^{p \times p}\) and \(R^{(k-b) \times (k-b)}\), respectively. (This definition is arbitrary and could be replaced by other choices.)

Define the elements of \(λ^S\) to be

\[
\begin{align*}
λ_{1,F}^S &= (τ_{1F1}, ..., τ_{\min\{k-b,p\}F1}, ..., τ_{1FT}, ..., τ_{\min\{k-b,p\}FT})' \in R^{\min\{k-b,p\}}, \\
λ_{2,F}^S &= (B_{F1}, ..., B_{FT}) \in R^{p \times T}, \\
λ_{3,F}^S &= (C_{F1}, ..., C_{FT}) \in R^{(k-b) \times T(k-b)}, \\
λ_{4,F}^S &= E_F G_i \in R^{k \times p}, \\
λ_{4,β,F}^S &= E_F G_{iβ} \in R^{k \times b}, \\
λ_{4,β_j,F}^S &= E_F G_{iβ_j} \in R^{k \times b} \text{ for } j = 1, ..., p, \\
λ_{4,β_j,β,F}^S &= E_F G_{iβ_j β} \in R^{k \times b} \text{ for } j = 1, ..., b, \\
λ_{5,β,F}^S &= E_F \left( \begin{pmatrix} g_i \\ vec(G_i) \end{pmatrix} \right) \left( \begin{pmatrix} g_i \\ vec(G_i) \end{pmatrix} \right)' \in R^{(p+1)k \times (p+1)k}, \\
λ_{6,β,F}^S &= E_F g_i g_{ij}^T \in R^{k \times k} \text{ for } j = 1, ..., b, \\
λ_{6,3,j,F}^S &= E_F g_i g_{ij} g_{ij}^T \in R^{k \times k} \text{ for } j = 1, ..., k, \\
λ_{6,F}^S &= (λ_{6,1F1}, ..., λ_{6,\min\{k-b,p\}-1}F1, ..., λ_{6,1FT}, ..., λ_{6,\min\{k-b,p\}-1}FT)' \\
&= \left( \frac{τ_{2F1}}{τ_{1F1}}, ..., \frac{τ_{\min\{k-b,p\}F1}}{τ_{\min\{k-b,p\}-1}F1}, ..., \frac{τ_{2FT}}{τ_{1FT}}, ..., \frac{τ_{\min\{k-b,p\}FT}}{τ_{\min\{k-b,p\}-1}FT} \right)' \in [0, 1]^{T(\min\{k-b,p\}-1)}, \\
λ_{7,F}^S &= U_{2F}, \\
λ_{8,F}^S &= F, \\
λ_{10,F}^S &= Var_F (g_i', vec(G_i)', vec(g_i g_i')', vec(G_{β_i})')', \\
λ^S &= λ_{F}^S := (λ_{1,F}^S, ..., λ_{10,F}^S), \\
\end{align*}
\]

(31.14)

where 0/0 := 0 for the components of \(λ_{6,F}^S\), and \(λ^S\) is the vector that collects all the above terms in one vector. As mentioned above, there is no weighting matrix \(\widehat{W}_n\) for the subvector test and therefore, no \(λ_{7,F}^S\) component appears. For \(j = 1, ..., b\), we denote the \(j\)-th column of \(λ_{4,β,F}^S \in R^{k \times b}\) by \(λ_{4,β_j,F}^S \in R^k\). Let

\[
\Lambda^S := \{λ_{F}^S : F \in 𝒵^S\}, \text{ and } \\
h_n(λ^S) := (n^{1/2}λ_{1,F}^S, λ_{2,F}^S, λ_{3,F}^S, λ_{4,F}^S, λ_{6,F}^S, λ_{8,F}^S, λ_{10,F}^S).
\]

(31.15)

Let \(\{λ_{n,h}^S \in \Lambda^S : n \geq 1\}\) denote a sequence \(\{λ_{n}^S \in \Lambda^S : n \geq 1\}\) for which \(h_n(λ_{n}^S) \rightarrow h \in H\),

126
for $H$ as in (16.2).\footnote{Regarding the notation, it would be more consistent to put a superscript $S$ on all of the expressions involving $h$. However, this would introduce too much clutter, so we do not do so.} Denote by $h_{4,\beta}$, $h_{4,\beta}^\alpha$, $h_{4,\beta}^{\beta,\beta}$, $h_{5,G}$, and $h_{5,G}$, the limits of $\lambda^S_{4,\beta,F_n}$, $\lambda^S_{4,\beta}^{\alpha,\beta,F_n}$, $\lambda^S_{4,\beta}^{\beta,\beta,F_n}$, $\lambda^S_{5,G,F_n}$, and $\lambda^S_{5,G,F_n}$ under the sequence $\{\lambda^S_{n,h} : n \geq 1\}$, respectively, and analogously for other expressions, where by $\lambda^S_{5,G,F}$ and $\lambda^S_{5,G,F_n}$ we denote the lower left and lower right submatrices of $\lambda^S_{5,F}$ of dimensions $R^{b \times k}$ and $R^{b \times pk}$.

Consider a sequence $\{\lambda^S_{n,h} : n \geq 1\}$ and let the distributions $\{F_n : n \geq 1\}$ correspond to $\{\lambda^S_{n,h} : n \geq 1\}$. Because under $\{\lambda^S_{n,h} : n \geq 1\}$, $(E_{F_n} g_i g'_i)^{-1/2} E_{F_n} G_{ij}$ converges to a full column rank matrix, there exists a smallest index $t^* \in \{1, ..., T\}$ such that for all $n$ sufficiently large the $b$ columns of $((E_{F_n} g_i g'_i)^{-1/2} E_{F_n} G_{ij})'$ indexed by $t^*$ form a basis of $R^b$, and by definition of $\{\lambda^S_{n,h} : n \geq 1\}$, $n^{1/2}(\tau_{F_n t^*}, ..., \tau_{\min(k-b,p)F_n t^*}) \rightarrow (h_{1,1 t^*}, ..., h_{1,\min(k-b,p) t^*})$. Note that $t^*$ depends on the sequence $\{\lambda^S_{n,h} \in \Lambda^S : n \geq 1\}$. We include $\tau_{F_1}$, $B_{F_1}$, and $C_{F_1}$ for all $t = 1, ..., T$ in the definition of $\lambda^S_{1,F}$, $\lambda^S_{2,F}$, and $\lambda^S_{3,F}$ in (31.14) because this ensures the convergence of $n^{1/2} \tau_{1,F_n t^*}$, $B_{F_n t^*}$, and $C_{F_n t^*}$ for the value $t^*$ just defined.

In what follows, with slight abuse of notation, we leave out the index $t^*$ from the notation.

As in (16.22), let $q^S = q^S_2 \in \{0, ..., \min\{k-b, p\}\}$ be such that

$$h_{1,j} = \infty \text{ for } 1 \leq j \leq q^S_2 \text{ and } h_{1,j} < \infty \text{ for } q^S_2 + 1 \leq j \leq \min\{k-b, p\},$$

(31.16)

where $h_{1,j} := \lim n^{1/2} \tau_{j,F_n} \geq 0$ for $j = 1, ..., \min\{k-b, p\}$.

Define $\mathcal{F}^S_{W_U}$ as $\mathcal{F}_{W_U}$ in (16.12) with $\mathcal{F}$ replaced by $\mathcal{F}^S$ and $W$ replaced by $I_k$. Define $\Lambda^S_{W_U}$ as $\Lambda_{W_U}$ in (16.17) with $\mathcal{F}_{W_U}$ replaced by $\mathcal{F}^S_{W_U}$.

**Assumption WUS for the parameter space $\Lambda^S_{W_U}$**: Under all subsequences $\{w_n\}$ and all sequences $\{\lambda^S_{w_n,h} : n \geq 1\}$ with $\lambda^S_{w_n,h} \in \Lambda^S$, (a) $\hat{U}_{2w_n} \rightarrow h_8 \ (:= \lim U_{2F_{w_n}})$ and (b) $U_1(\cdot)$ is a continuous function at $h_8$ on some set $\mathcal{U}_2$ that contains $\{u_{k,F}^S (= U_{2F}) : \lambda^S \in \Lambda^S\}$ and contains $\hat{U}_{2w_n} \\text{ wp-1}$.

As in (16.23), let (and recall again that we leave out the index $t^*$ from the notation)

$$S_n := \text{Diag}\{(n^{1/2} \tau_{1,F_n})^{-1}, ..., (n^{1/2} \tau_{q^S,F_n})^{-1}, 1, ..., 1\} \in R^{p \times p} \text{ and } T_n := B_{F_n} S_n \in R^{p \times p}.$$ (31.17)

The random function $CLR_{k,p}(D, J)$ in (9.12) that generates the conditional critical value of the CLR subvector test can be expressed as follows. Suppose $M_J = O^O$, for $O$ defined in (31.5).
Then, we can write

\[
\text{CLR}_{k,p}(D, J) := Z' M_J Z - \lambda_{\min}((Z, D)' M_J (Z, D)) \\
= (O'Z)'O'Z - \lambda_{\min}((O'Z, O'D)'(O'Z, O'D)) \\
= Z'Z - \lambda_{\min}((Z, O'D)'(Z, O'D)),
\]

\[
\sim \text{CLR}_{k-b,p}(O'D, 0^{(k-b)\times 0}) = \text{CLR}_{k-b,p}(O'D),
\]

(31.18)

where \(Z \sim N(0^k, I_k), Z := O'Z \sim N(0^{k-b}, I_{k-b}), \sim \) denotes “has the same distribution as,” and \(\text{CLR}_{k-b,p}(O'D)\) is the expression from the full vector test defined in (5.8).

We now state the intermediate lemmas, propositions, and theorems upon which the proof of Theorem 9.1 is based. Using them, the proof of Theorem 9.1 follows the same lines as the proof of Theorem 16.1 for the full vector case.

By Lemma 16.2, the \(1 - \alpha\) quantile \(c_{k-b,p}(O'D, 1 - \alpha)\) of \(\text{CLR}_{k-b,p}(O'D)\) depends on \(O'D\) only through the singular values of \(O'D\). By (31.18), that immediately implies the following analogue to Lemma 16.2.

**Lemma 31.1** Let \(D\) and \(J\) be \(k \times p\) and \(k \times b\) matrices, respectively, where \(J\) has full column rank \(b\). Let CYB' denote a singular value decomposition of \(O'D \in R^{(k-b)\times p}\), where \(Y\) contains the singular values in nonincreasing order and \(O' = O(J)'\) is defined in (31.5). Then, \(c_{k,p}(D, J, 1 - \alpha)\) depends on \(D\) and \(J\) only through \(Y\) and

\[
c_{k,p}(D, J, 1 - \alpha) = c_{k-b,p}(Y, 0^{(k-b)\times 0}, 1 - \alpha) = c_{k-b,p}(Y, 1 - \alpha).
\]

Just like the full vector test in Lemma 5.1, the subvector CQLR test is invariant to nonsingular transformations of the moment functions. We suppress the dependence on \(\theta_0\) of the statistics in the following lemma.

**Lemma 31.2** Given the preliminary estimator \(\hat{\beta}_n\) of \(\beta_n^*\), the statistics \(\text{AP}_{n}^{S}(\hat{\beta}_n), \text{QLR}_{n}^{S}(\hat{\beta}_n), \hat{\beta}_n,\)

\[
c_{k,p}(n^{1/2}D_n(\hat{\beta}_n), \tilde{J}_n(\hat{\beta}_n), 1-\alpha), \tilde{D}_n^s(\hat{\beta}_n)M_{\tilde{J}_n(\hat{\beta}_n)}\tilde{D}_n^s(\hat{\beta}_n), \tilde{g}_n(\hat{\beta}_n)'\tilde{\Omega}_n^{-1/2}(\hat{\beta}_n)M_{\tilde{J}_n(\hat{\beta}_n)}\tilde{D}_n^s(\hat{\beta}_n), \tilde{\Sigma}_n(\hat{\beta}_n),
\]

and \(\tilde{L}_n(\hat{\beta}_n)\) are invariant to the transformation \((g_i(\beta), G_i(\beta)) \sim (Mg_i(\beta), MG_i(\beta)) \forall i \leq n\) for any \(k \times k\) nonsingular matrix \(M\). This transformation induces the following transformations: \(\tilde{g}_n(\hat{\beta}_n) \sim MG_n(\hat{\beta}_n), \tilde{G}_n(\hat{\beta}_n) \sim MG_n(\hat{\beta}_n), \tilde{G}_n(\hat{\beta}_n) \sim MG_n(\hat{\beta}_n), \tilde{\Omega}_n(\hat{\beta}_n) \sim M\tilde{\Omega}_n(\hat{\beta}_n) M', \tilde{\Sigma}_n(\hat{\beta}_n) \sim (I_{p+1} \otimes M)\tilde{\Sigma}_n(\hat{\beta}_n) \times (I_{p+1} \otimes M')\), and \(\tilde{\tilde{L}}_n(\hat{\beta}_n) \sim (I_{p+1} \otimes M)\tilde{\tilde{L}}_n(\hat{\beta}_n) (I_{p+1} \otimes M')\).
The proof of the lemma is straightforward for all quantities except \(c_{k,p}(n^{1/2}\tilde{D}_n(\tilde{\beta}_n), J_n(\tilde{\beta}_n), 1 - \alpha)\). Using Lemma 31.1, this quantity depends on \(n^{1/2}\tilde{D}_n(\tilde{\beta}_n)\) and \(J_n(\tilde{\beta}_n)\) only through the nonzero singular values of \(O(j_n(\tilde{\beta}_n)^t)n^{1/2}\tilde{D}_n(\tilde{\beta}_n)^t\), which equal the square roots of the nonzero eigenvalues of \(n^{1/2}\tilde{D}_n(\tilde{\beta}_n)^tM_{J_n(\tilde{\beta}_n)}n^{1/2}\tilde{D}_n(\tilde{\beta}_n)\). But, the latter quantity is invariant to the transformation \((g_i(\beta), G_i(\beta)) \sim (Mg_i(\beta), MG_i(\beta))\).

The derivation in (31.18) immediately implies an analogue of the result in Lemma 27.2. Let \(c_{k-b,p,q}(\tau^{c}_{\infty}, 1 - \alpha)\) denote the \(1 - \alpha\) quantile of

\[
ACLR_{k-b,p,q}(\tau^{c}_{\infty}) := Z'Z - \lambda_{\min}((\Upsilon(\tau^{c}_{\infty}), \bar{Z}_2)')'(\Upsilon(\tau^{c}_{\infty}), \bar{Z}_2)),
\]

where \(Z := \begin{pmatrix} \bar{Z}_1 \\ \bar{Z}_2 \end{pmatrix} \sim N(0^{k-b}, I_{k-b})\) for \(\bar{Z}_1 \in \mathbb{R}^q\) and \(\bar{Z}_2 \in \mathbb{R}^{k-b-q}\),

\[
\tau^{c}_{\infty} := (\tau^{c}_{(q+1)\infty}, \ldots, \tau^{c}_{\min(k-b,p)\infty})' \in \mathbb{R}^{\min(k-b,p)-q},
\]

\[
\Upsilon(\tau^{c}_{\infty}) := \begin{pmatrix} \text{Diag}(\tau^{c}_{\infty}) \\ 0^{(k-b-p)\times(p-q)} \end{pmatrix} \in \mathbb{R}^{(k-b-q)\times(p-q)} \text{ if } k - b \geq p, \text{ and}
\]

\[
\Upsilon(\tau^{c}_{\infty}) := \begin{pmatrix} \text{Diag}(\tau^{c}_{\infty}) \\ 0^{(k-b-q)\times(p-k)} \end{pmatrix} \in \mathbb{R}^{(k-b-q)\times(p-k)} \text{ if } k - b < p.
\]

**Lemma 31.3** Suppose \(\{(D^c_n, J^c_n) : n \geq 1\}\) is a sequence of constant (i.e., nonrandom) \(k \times p\) and \(k \times b\) matrices, respectively, such that \(O^c_nD^c_n\) (for \(O^c_nO^c_n = M_{J_n}\) and \(O^c_n\) defined in (31.5)) has singular values \(\{\tau^{c}_{jn} \geq 0 : j \leq \min\{k-b,p\}\}\) for \(n \geq 1\) that satisfy (i) \(\{\tau^{c}_{jn} \geq 0 : j \leq \min\{k-b,p\}\}\) are nonincreasing in \(j\) for \(n \geq 1\), (ii) \(\tau^{c}_{jn} \to \infty\) for \(j \leq q\) for some \(0 \leq q \leq \min\{k-b,p\}\) and (iii) \(\tau^{c}_{jn} \to 0^c_{\infty} < \infty\) for \(j = q + 1, \ldots, \min\{k-b,p\}\). Then,

\[
c_{k,p}(D^c_n, J^c_n, 1 - \alpha) \to c_{k-b,p,q}(\tau^{c}_{\infty}, 1 - \alpha).
\]

The next lemma is a restatement of Lemma 27.3 with \(k\) replaced by \(k - b\).

**Lemma 31.4** For all admissible integers \((k-b,p,q)\) (i.e., \(k-b \geq 1, p \geq 1,\) and \(0 \leq q \leq \min\{k-b,p\}\)) and all \(\min\{k-b,p\} - q \geq 0\) vectors \(\tau^{c}_{\infty}\) with nonnegative elements in nonincreasing order, the df of \(ACLR_{k-b,p,q}(\tau^{c}_{\infty}) := Z'Z - \lambda_{\min}((\Upsilon(\tau^{c}_{\infty}), \bar{Z}_2)')'(\Upsilon(\tau^{c}_{\infty}), \bar{Z}_2))\) is continuous and strictly increasing at its \(1 - \alpha\) quantile \(c_{k-b,p,q}(\tau^{c}_{\infty}, 1 - \alpha)\) for all \(\alpha \in (0, 1)\), where \(Z := (Z_1, Z_2)' \sim N(0^{k-b}, I_{k-b})\) for \(Z_1 \in \mathbb{R}^q\) and \(Z_2 \in \mathbb{R}^{k-b-q}\) and \(\tau^{c}_{\infty}\) and \(\Upsilon(\tau^{c}_{\infty})\) are defined in (31.19).

The next lemma is an important ingredient in the proof of Theorem 9.1 because it provides the asymptotic distributions of key quantities. It is the analogue and extension of Lemma 16.4 for the subvector test. We now introduce some notation that is used in the lemma.
By the Lyapunov CLT, under sequences \( \{\lambda_{n,h}^S \in \Lambda^S : n \geq 1\} \), we have

\[
\begin{pmatrix}
g_i \\
vec(G_i) \\
vec(g_i g_i' - \Omega_n) \\
vec(G_{ji} - E_n G_{ji})
\end{pmatrix} \rightarrow_d \mathcal{T}_h \sim N(0^{d^*}, h_{10}),
\]

where \( d^* = k + kp + k^2 + kb \), and the function \( vec_{k,p}^{-1}(\cdot) \) is the inverse of the \( vec(\cdot) \) function for \( k \times p \) matrices. (Thus, the domain of \( vec_{k,p}^{-1}(\cdot) \) consists of \( kp \)-vectors and its range consists of \( k \times p \) matrices.) As defined in (31.20), \( \bar{g}_h \) is the same as in (16.21) for the full vector case.

The asymptotic distributions of (i) \( n^{1/2}(\bar{\beta}_n - \beta_n^*) \), (ii) \( n^{1/2}\tilde{g}_n(\bar{\beta}_n) \), (iii) \( n^{1/2}vec(D_n(\bar{\beta}_n) - D_n) \), where \( D_n := E_n G_i \), (iv) \( n^{1/2}(\tilde{\Omega}_n(\bar{\beta}_n) - \Omega_n) \), and (v) \( n^{1/2}(\tilde{G}_{\beta_n}(\bar{\beta}_n) - E_n G_{\beta_j}) \) are given by

(i) \( \bar{\beta}_h := [(h_{5,g}^{-1/2} h_{4,}\bar{\beta}')(h_{5,g}^{-1/2} h_{4,\beta})]^{-1}(h_{5,g}^{-1/2} h_{4,\beta})' h_{5,g}^{-1/2} \bar{g}_h \),

(ii) \( \bar{g}_h^S := h_{5,g}^{1/2} M_{h_{5,g}^{-1/2} h_{4,\beta}} h_{5,g}^{-1/2} \bar{g}_h \),

(iii) \( vec(D_h^S) := (vec(C_h) - h_{5,g} h_{5,g}^{-1} \tilde{g}_h) + vec(h_{4,\beta} \bar{\beta}_h, \ldots, h_{4,\beta} \bar{\beta}_h) - h_{5,g} h_{5,g}^{-1} h_{4,\beta} \bar{\beta}_h \),

(iv) \( \overline{\beta}_h := (\overline{\beta}_{h,1}, \ldots, \overline{\beta}_{h,k}) \), and

(v) \( \overline{g}_h^S := (\overline{g}_{h,1}^S, \ldots, \overline{g}_{h,b}^S) \) where

\[
\overline{\beta}_{h,j} := \mathcal{L}_{j,h,3} - h_{5,3,\beta j} h_{5,3,\beta j}^{-1} \bar{g}_h + [(h_{5,3,\beta j}, \ldots, h_{5,3,\beta j}) + ((h_{5,3,\beta j}', \ldots, (h_{5,3,\beta j}'(j) = h_{5,3,\beta j} h_{5,3,\beta j}^{-1} h_{4,\beta} \bar{\beta}_h)

for \( j = 1, \ldots, k \),

\[
\overline{g}_{h,j} := \mathcal{L}_{j,h,4} - h_{5,\beta j} h_{5,\beta j}^{-1} \bar{g}_h + (h_{4,\beta j} - h_{5,\beta j} h_{5,\beta j}^{-1} h_{4,\beta j}) \bar{\beta}_h \]

for \( j = 1, \ldots, b \).
the matrix of partial derivatives of that mapping evaluated at vec(h_{5,g}^{-1/2}h_{4,\beta}).

The asymptotic distributions of (vi) $n^{1/2}(\Omega_n^{-1/2}(\tilde{\beta}_n) - \Omega_n^{-1/2})$, (vii) $n^{1/2}(\Omega_n^{-1/2}(\tilde{\beta}_n) - \Omega_n^{-1/2}E_nG_{\beta})$, (viii) $n^{1/2}(\Omega_n^{-1/2}(\tilde{\beta}_n) - O_n\Omega_n^{-1/2}D_n)$, (ix) $n^{1/2}(\Omega_n^{-1/2}(\tilde{\beta}_n) - O_n\Omega_n^{-1/2}D_n)$, (x) $n^{1/2}(\Omega_n^{-1/2}(\tilde{\beta}_n) - O_n\Omega_n^{-1/2}D_n) \times U_n B_n S_n$ are given by

$$(vi) \ vec_{k,k}^{-1}(\Xi_h vec(\Xi^S_h)),$$

$$(vii) \Xi^S_h := h_{5,g}^{-1/2}D^S_h + vec_{k,k}(\Xi_h vec(\Xi^S_h))h_{4,\beta},$$

$$(viii) \ vec_{k,k-b}(\Xi_h vec(\Xi^S_h)),$$

$$(ix) \chi_h := vec_{k,k-b}(\Xi_h vec(\Xi^S_h))'h_{5,g}^{-1/2}h_4 + O(h_{5,g}^{-1/2}h_{4,\beta})vec_{k,k}(\Xi_h vec(\Xi^S_h))h_4$$
$$+ O(h_{5,g}^{-1/2}h_{4,\beta})'h_{5,g}^{-1/2}\Xi_h,$$

$$(x) \Xi^S_{h,q} := (\Xi^S_{h,q}, \Xi^S_{h,p-q}),$$

where $\Xi^S_{h,q} := h_{3,q} S \in R^{(k-b) \times q}$,

$$\Xi^S_{h,p-q} := h_{3} h_{1, p-q} + \chi_h h_{8} h_{2, p-q} S \in R^{(k-b) \times (p-q)}, \quad (31.22)$$

and $h_{1, p-q} \in R^{(k-b) \times (p-q)}$ is defined as in [16.24] with $k - b$ and $q$ in place of $k$ and $q$, respectively.\footnote{See (31.56) for (vi), (31.57) for (vii), (31.59) for (viii), (31.64) for (ix), and (31.60), (31.61), and (31.65) for (x). Recall again that we leave out a subindex $t^*$ from certain expressions.}

**Lemma 31.5** Suppose Assumptions gb and WUS hold for some non-empty parameter space $\Lambda^S_\text{WU}$. Under all sequences $\{\lambda_{n,h} \in \Lambda^S_\text{WU} : n \geq 1\}$,

(a) $n^{1/2}(\tilde{\beta}_n - \beta^*_n) \rightarrow_d \Xi_h,$

(b) $\tilde{\beta}_n \rightarrow_d h_{5,g}^{-1/2}h_{4,\beta},$

(c)

$$n^{1/2} \begin{pmatrix} \tilde{g}_n(\theta_0, \tilde{\beta}_n) \\ \tilde{D}_n(\theta_0, \tilde{\beta}_n) - E_{F_n} G_i \\ \tilde{\Omega}_n(\theta_0, \tilde{\beta}_n) - E_{F_n} G_i G_i' \\ \tilde{G}_{\beta n}(\theta_0, \tilde{\beta}_n) - E_{F_n} G_{i\beta} \end{pmatrix} \rightarrow_d \begin{pmatrix} \Xi^S_h \\ \Xi^S_h \\ \Xi^S_h \\ \Xi^S_h \end{pmatrix},$$

where $(\Xi_h, \Xi^S_h, \Xi^S_h, \Xi^S_h)$ and $\Xi^S_h$ are independent,

(d) for $\tilde{\Omega}_{F_n}$ defined in [31.10],

$$n^{1/2}\tilde{\Omega}_{F_n}\Omega_n^{-1/2}(\theta_0, \tilde{\beta}_n)D_n(\theta_0, \tilde{\beta}_n) U_{F_n} T_n \rightarrow_d \Xi^S_h \in R^{(k-b) \times p},$$

where $(\Xi_h, \Xi^S_h, \Xi^S_h, \Xi^S_h)$ and $\Xi^S_h$ are independent, and

(e) under all subsequences $\{w_n\}$ and all sequences $\{\lambda_{w_n,h} : n \geq 1\}$ with $\lambda_{w_n,h} \in \Lambda^S_\text{WU}$, the convergence results in parts (a)-(d) hold with $n$ replaced with $w_n$.\footnote{See (31.56) for (vi), (31.57) for (vii), (31.59) for (viii), (31.64) for (ix), and (31.60), (31.61), and (31.65) for (x). Recall again that we leave out a subindex $t^*$ from certain expressions.
Lemma 31.5 is proved in Section 31.2 below. Note that in order to obtain consistency of the first step estimator $\tilde{\beta}_n$ we only need to impose the conditions in $\mathcal{F}_{AR,1}^S$. In particular, for consistency of $\tilde{\beta}_n$, the variance matrix $\Omega_{F_n}$ is allowed to be rank deficient. Lemma 31.5(b) and (c) implies Theorem 9.1 for the subvector AR test. This holds because $AR_n^S(\theta_0, \tilde{\beta}_n)$ is a quadratic form in $M_{\beta_n}^{-1/2}(\theta_0, \tilde{\beta}_n)n^{1/2}g_n(\theta_0, \tilde{\beta}_n)$ which converges in distribution to $M_{h_{5,g}^{-1/2}h_{4,b}^{-1/2}gh}$.

Because $h_{5,g}^{-1/2}h_{4,b}$ has full column rank $b$, the desired result follows.

An analogue of Proposition 16.5 holds where $\tilde{W}_n, W_{F_n}$ and $\hat{D}_n \in R^{k \times p}$ are replaced by $I_k, I_k, \text{ and } \tilde{O}'_Fn^{-1/2}(\theta_0, \tilde{\beta}_n)\hat{D}_n(\theta_0, \tilde{\beta}_n) \in R^{(k-b) \times p}$, respectively. In particular, $\tilde{\kappa}_{jn}$ is defined as the $j$-th eigenvalue of

$$n(\tilde{O}'_F \tilde{\Omega}^{-1/2}_n(\theta_0, \tilde{\beta}_n)\hat{D}_n(\theta_0, \tilde{\beta}_n)\tilde{U}_n)(\tilde{O}'_F \tilde{\Omega}^{-1/2}_n(\theta_0, \tilde{\beta}_n)\hat{D}_n(\theta_0, \tilde{\beta}_n)\tilde{U}_n).$$

Recall the following notation as for the full vector test, $B_{F_n} = (B_{F_n,q}^S, B_{F_n,p-q}^S)$, $C_{F_n} = (C_{F_n,q}^S, C_{F_n,k-b-q}^S)$, with $B_{F_n,q}^S \in R^{p \times q^S}$, $B_{F_n,p-q}^S \in R^{p \times (p-q^S)}$, $C_{F_n,q}^S \in R^{(k-b) \times q^S}$, and $C_{F_n,k-b-q}^S \in R^{(k-b) \times (k-b-q^S)}$ and corresponding decompositions for the limiting matrices $h_2 = (h_{2,q}^S, h_{2,p-q}^S)$ and $h_3 = (h_{3,q}^S, h_{3,k-b-q}^S)$. Recall that we leave out a subindex $t^*$ from certain expressions.

**Proposition 31.6** Suppose Assumption WU$^S$ holds for some non-empty parameter space $\Lambda_*^S \subset \Lambda_{WU}^S$. Under all sequences $\{\lambda_{n,h}^S : n \geq 1\}$ with $\lambda_{n,h}^S \in \Lambda_*^S$,

(a) $\tilde{\kappa}_{jn} \rightarrow_p \infty$ for all $j \leq q^S$,

(b) $(\tilde{\kappa}_{(q^S+1)n}, ..., \tilde{\kappa}_{pn})'$ converges in distribution to the (ordered) $p - q^S$ vector of the eigenvalues of $\tilde{\Delta}_h^{S'}q^S_{h,b-q^S}h_{3,k-b-q^S}^{S} \tilde{\Delta}_h^{S}\tilde{\Delta}_q^{S'}h_{3,k-b-q^S}^{S} \in R^{(p-q^S) \times (p-q^S)}$,

(c) the convergence in parts (a) and (b) holds jointly with the convergence in Lemma 31.5, and

(d) under all subsequences $\{w_n\}$ and all sequences $\{\lambda_{w_n,h}^S : n \geq 1\}$ with $\lambda_{w_n,h}^S \in \Lambda_*^S$, the results in parts (a)-(c) hold with $n$ replaced with $w_n$.

An analogue of Theorem 16.6 holds for $QLRS_{WU,n}^S = AR_n^S(\theta_0, \tilde{\beta}_n) - \lambda_{\min}(n\tilde{Q}_{WU,n}^S)$, defined in (31.1). For $\tilde{\eta} := (\theta_0, \tilde{\beta}_n), \text{ wp} \rightarrow 1$, we can write $\tilde{Q}_{WU,n} = \left(\tilde{O}'_F \tilde{\Omega}^{-1/2}_n(\tilde{\eta})\hat{D}_n(\tilde{\eta})\tilde{U}_n, \tilde{O}'_F n^{-1/2}(\tilde{\eta})\tilde{g}_n(\tilde{\eta})\right)' \left(\tilde{O}'_F n^{-1/2}(\tilde{\eta})\hat{D}_n(\tilde{\eta})\tilde{U}_n, \tilde{O}'_F \tilde{\Omega}^{-1/2}_n(\tilde{\eta})\tilde{g}_n(\tilde{\eta})\right)$ by again replacing $\tilde{W}_n, W_{F_n}, \tilde{\Omega}^{-1/2}_n\tilde{g}_n$, and $\hat{D}_n \in R^{k \times p}$ by $I_k, I_k, \tilde{O}'_F \tilde{\Omega}^{-1/2}_n(\tilde{\eta})\tilde{g}_n(\tilde{\eta})$, and $\tilde{O}'_F \tilde{\Omega}_n(\theta_0, \tilde{\beta}_n)^{-1/2}\hat{D}_n(\theta_0, \tilde{\beta}_n) \in R^{(k-b) \times p}$, respectively. This implies that the role of $k$ is played by $k-b$. Note that by Lemma 31.5(b) and (c) and (31.59) below, which implies $\tilde{O}'_F = O(\tilde{J}_n(\theta_0, \tilde{\beta}_n))' \rightarrow_p$.

132
\(O(h_{5,g}^{-1/2}h_{4,\beta})\), we have

\[
n^{-1/2} \tilde{F}_n - n^{-1/2}(\bar{y}) \tilde{g}_n(\bar{y}) \to_d O(h_{5,g}^{-1/2}h_{4,\beta})'h_{5,g}^{-1/2}\bar{g}_h = O(h_{5,g}^{-1/2}h_{4,\beta})'h_{5,g}^{-1/2}\bar{g}_h = \mathcal{N}(0^{k-b}, I_{k-b}), \tag{31.25}
\]

using \(\bar{g}_h^S := h_{5,g}^{-1/2}M_{h_{5,g},h_{4,\beta}}^{-1/2}\bar{g}_h\), \(OO' = M_{h_{5,g},h_{4,\beta}}^{-1/2}\), and \(O'O = I_{k-b}\).

**Theorem 31.7** Suppose Assumption WUS holds for some non-empty parameter space \(\Lambda^S_\epsilon \subset \Lambda^S_{WU}\). Under all sequences \(\{\lambda^S_{n,h} : n \geq 1\}\) with \(\lambda^S_{n,h} \in \Lambda^S_\epsilon\),

\[
QLR^S_{WU,n} \to_d l'h_h - \lambda_{\min}((\Delta^S_{h,p-q^S}, l_h)' h_{3,k-b-q^S} h_{3,k-b-q^S} (\Delta^S_{h,p-q^S}, l_h)), \quad \text{where}
\]

\[l_h := O(h_{5,g}^{-1/2}h_{4,\beta})'h_{5,g}^{-1/2}\bar{g}_h,\]

\(\Delta^S_{h,p-q^S}\) is defined in \(31.22\), and the convergence holds jointly with the convergence in Lemma 31.5 and Proposition 31.6. When \(q^S = p\) (which can only hold if \(k - b \geq p\) because \(q^S \leq \min\{k - b, p\}\)), \(\Delta^S_{h,p-q^S}\) does not appear in the limit random variable and the limit random variable reduces to

\[
l'h_h h_{3,p} h_{3,p} l_h \sim \chi^2_p.
\]

When \(q^S = k - b\) (which can only hold if \(k - b \leq p\)), the \(\lambda_{\min}(\cdot)\) expression does not appear in the limit random variable and the limit random variable reduces to

\[
l'h_h l_h \sim \chi^2_{k-b}. \tag{31.26}
\]

When \(k - b \leq p\) and \(q^S < k - b\), the \(\lambda_{\min}(\cdot)\) expression equals zero and the limit random variable reduces to the one in \(31.26\). Under all subsequences \(\{w_n\}\) and all sequences \(\{\lambda^S_{w_n,h} : n \geq 1\}\) with \(\lambda^S_{w_n,h} \in \Lambda^S_\epsilon\), the same results hold with \(n\) replaced with \(w_n\).

The following lemma, which the proof of Theorem 31.7 relies on, adapts Lemma 26.1 from the full vector test and Lemma 17.1 in AG1. Define

\[
\Upsilon_n := \begin{bmatrix} \Upsilon_{n,q^S} & 0^{q^S \times (p-q^S)} \\ 0^{(p-q^S) \times q^S} & \Upsilon_{n,p-q^S} \\ 0^{(k-b-p) \times q^S} & 0^{(k-b-p) \times (p-q^S)} \end{bmatrix} \in \mathbb{R}^{(k-b) \times p} \text{ if } k - b \geq p, \tag{31.27}
\]

\[
\Upsilon_n := \begin{bmatrix} \Upsilon_{n,q^S} & 0^{q^S \times (k-b-q^S)} & 0^{q^S \times (p - (k-b))} \\ 0^{(k-b-q^S) \times q^S} & \Upsilon_{n,k-b-q^S} & 0^{(k-b-q^S) \times (p - (k-b))} \end{bmatrix} \in \mathbb{R}^{(k-b) \times p} \text{ if } k - b < p,
\]

133
as in [25.2], but with $\tau_{1,F_n^\ast}, \ldots, \tau_{p,F_n^\ast}$ and $q^S$ in place of $\tau_{1,F_n}, \ldots, \tau_{p,F_n}$ and $q$, respectively. Define

\[
\begin{align*}
\hat{D}^+_n &:= (\hat{\Omega}'_n \hat{\Omega}_{n}^{-1/2} (\theta_0, \hat{\beta}_n) \hat{D}_n(\theta_0, \hat{\beta}_n), \hat{\Omega}'_n \hat{\Omega}_{n}^{-1/2} \hat{g}_n) \in \mathbb{R}^{(k-b)\times(p+1)}, \\
\hat{U}^+_n &:= \begin{bmatrix} \hat{U}_n & 0^{p\times1} \\ 0^{1\times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1)\times(p+1)}, U^+_n = \begin{bmatrix} U_n & 0^{p\times1} \\ 0^{1\times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1)\times(p+1)}, \\
h_{81}^+ &:= \begin{bmatrix} h_{81} & 0^{p\times1} \\ 0^{1\times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1)\times(p+1)}, B^+_n = \begin{bmatrix} B_n & 0^{p\times1} \\ 0^{1\times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1)\times(p+1)}, \\
B^+_n &:= (B^+_{n,q^S}, B^+_{n,p+1-q^S}) \text{ for } B^+_{n,q^S} \in \mathbb{R}^{(p+1)\times q^S} \text{ and } B^+_{n,p+1-q^S} \in \mathbb{R}^{(p+1)\times(p+1-q^S)}, (31.28) \\
D^+_n &:= (O(J_n)' \Omega_n^{-1/2} D_n, 0^k) \in \mathbb{R}^{(k-b)\times(p+1)}, \ Y^+_n := (\mathbb{Y}_n, 0^{k-b}) \in \mathbb{R}^{(k-b)\times(p+1)}, \\
S^+_n &:= \text{Diag}\{((n^{1/2}\tau_{1,F_n})^{-1}, \ldots, (n^{1/2}\tau_{q^SF_n})^{-1}, 1, \ldots, 1\} = \begin{bmatrix} S_n & 0^{p\times1} \\ 0^{1\times p} & 1 \end{bmatrix} \in \mathbb{R}^{(p+1)\times(p+1)},
\end{align*}
\]

with $J_n$ defined in [31.8]. Let

\[
\kappa^+_jn \text{ denote the } j\text{th eigenvalue of } n\hat{U}^+_n \hat{D}^+_n \hat{U}^+_n \hat{D}^+_n \hat{U}^+_n, \forall j = 1, \ldots, p + 1, (31.29)
\]

ordered to be nonincreasing in $j$.

**Lemma 31.8** Suppose Assumption WUS holds for some non-empty parameter space $\Lambda^S_{w^S} \subset \Lambda^S_{WU}$. Under all sequences $\{\lambda^S_{n,h} : n \geq 1\}$ with $\lambda^S_{n,h} \in \Lambda^S_\ast$ for which $q^S$ satisfies $q^S \geq 1$, we have (a) $\kappa^+_jn \to_p \infty$ for $j = 1, \ldots, q^S$ and (b) $\kappa^+_jn = o_p((n^{1/2}r_{\ell,F_n})^2)$ for all $\ell \leq q^S$ and $j = q^S + 1, \ldots, p + 1$. Under all subsequences $\{w_n\}$ and all sequences $\{\lambda^S_{w_n,h} : n \geq 1\}$ with $\lambda^S_{w_n,h} \in \Lambda^S_{w^S}$, the same result holds with $n$ replaced with $w_n$.

The proof of Lemma 17.1, with analogous modifications that were made in order to prove Lemma [26.1], applies to prove Lemma [31.8]. For example, the equivalent of (17.3) of AG1 is

\[
\tau_{1,F_n}^{-1} \hat{D}^+_n U^+_n B^+_n = \tau_{1,F_n}^{-1} D^+_n U^+_n B^+_n + (n^{1/2}r_{1,F_n})^{-1} n^{1/2}(\hat{D}^+_n - D^+_n) U^+_n B^+_n = \tau_{1,F_n}^{-1} O(J_n)' \Omega_n^{-1/2} D_n U_n B_n, 0^{k-b} + O_p((n^{1/2}r_{1,F_n})^{-1}) = \tau_{1,F_n}^{-1} C_n \mathbb{Y}^+_n + O_p((n^{1/2}r_{1,F_n})^{-1})
\]

\[
\to_p h_3 \begin{bmatrix} h_{6,r_1^S}^\circ & 0^{r_1^S\times(p+1-r_1^S)} \\ 0^{(k-b-r_1^S)\times r_1^S} & 0^{(k-b-r_1^S)\times(p+1-r_1^S)} \end{bmatrix}, \text{ where } h_{6,r_1^S}^\circ := \text{Diag}\{1, h_{6,1}, h_{6,1}h_{6,2}, \ldots, \prod_{\ell=1}^{r_1^S-1} h_{6,\ell}\}
\]

and the second equality uses $n^{1/2}(\hat{D}^+_n - D^+_n) = O_p(1)$, which holds by [31.62] below and Lemma
31.5 (b). Note that here, unlike in the fourth line of (17.3) of AG1, no $o_p(1)$ term arises. Also recall again that we leave out the subindex $t^*$ from the notation, e.g. in $h_{6,j}$ for $j = 1, \ldots, r_1^2 - 1$.

As mentioned above, the proof of Theorem 9.1 now follows the same lines as the proof of Theorem 16.1 for the full vector case. The roles of $k, h_{5,q}^{-1/2} \tilde{y}_n, n^{1/2} \hat{W}_n \hat{D}_n \hat{U}_n$, and $\sum_{h,p-q} h_{3,k-q} h_{3,k-q}^t \hat{D}_n(\theta, \beta_n)$ in the proof of Theorem 16.1 are played by $k - b, l_b$ (defined in Theorem 31.7), $n^{1/2} \tilde{O}_F, \Omega_n^{-1/2}(\theta, \beta_n) \times \hat{D}_n(\theta, \beta_n) \hat{U}_n$, and $\sum_{h,p-q} h_{3,k-b-q} h_{3,k-b-q}^t \Omega_n^{31.3}$, respectively. By Lemma 31.1, the almost sure representation argument used in the proof of the full vector result, and Lemma 31.3, we have

\[
\begin{align*}
&c_{k,p}(n^{1/2} \Omega_n^{-1/2}(\theta, \beta_n) \hat{D}_n(\theta, \beta_n) \hat{U}_n, \hat{J}_n(\theta, \beta_n), 1 - \alpha) \\
&= c_{k-b,p}(\tilde{Y}_n, (k-b) \times 0, 1 - \alpha) \\
&= c_{k-b,p}(\tilde{Y}_n, 1 - \alpha) \\
&\rightarrow d c_{k-b,p,q}(h_{3,k-b-q}^t \Omega_n^{31.3}, 1 - \alpha),
\end{align*}
\]

(31.31)

where $\tilde{Y}_n$ denotes the matrix of singular values of $n^{1/2} \tilde{O}_F \Omega_n^{-1/2}(\theta, \beta_n) \hat{D}_n(\theta, \beta_n) \hat{U}_n$, defined as in (27.8), $c_{k-b,p,q}(\cdot, 1 - \alpha)$ is defined in (31.19) and $c_{k-b,p,q}(h_{3,k-b-q}^t \Omega_n^{31.3}, 1 - \alpha)$ uses the notation in (27.12), and the convergence in (31.31) is joint with the convergence in Theorem 31.7.

To conclude the proof of Theorem 9.1, we state the equivalent of Lemma 27.4 for the subvector case, which verifies that Assumption WUS holds when $\hat{U}_n$ is defined as $\hat{L}_n^{1/2}$, where $\hat{L}_n := (\theta, I_p)(\Sigma_n^{31.3}(\theta, \beta_n))^{-1}(\theta, I_p) \in \mathbb{R}^{p \times p}$ is defined in (9.11). Furthermore, the following lemma shows that $\mathcal{F}^S = \mathcal{F}_W^S$, where $\mathcal{F}^S$ is defined in (9.17) and $\mathcal{F}_W^S$ is defined just below (31.16). Recall the definition $\Sigma_{j\ell}(\Omega_F, R_F) := \text{tr}(R_j^{1/2})^{\Omega_F^{-1}}/k$ for the $(j, \ell)$-th component of $\Sigma$, where $\Omega_F := (g_j g_j^t, V_F := E_F(f_i - E_F f_i)(f_i - E_F f_i)' \in \mathbb{R}^{p+1 \times k} \times (p+1)^k)$, $R_F := (B' \otimes I_k)V_F(B \otimes I_k) \in \mathbb{R}^{(p+1)k \times (p+1)^k}$ in (16.7). Also, recall the definition of $\tilde{R}_n(\theta, \beta_n) := (B' \otimes I_k)\tilde{V}_n(\theta, \beta_n)(B \otimes I_k)$, which is given by (5.3) with $h_{\theta, \beta, n}$ in place of $\theta$.

**Lemma 31.9** (a) Assumption WUS holds with $\hat{U}_2 := n^{1/2}(\Omega_n^{31.3}(\theta, \beta_n), \hat{R}_n(\theta, \beta_n))$, $U_1(U_2)$ = $U_1(\Omega_F, R_F) = ((\theta, I_p)(\Sigma(\Omega_F, R_F))^{-1}(\theta, I_p))^{1/2}$ defined in (16.8), and $h = \lim U_2 \in \mathbb{R}^{p \times p}$, under any sequence $\{\lambda_{w_n,h} \in \Lambda_n : n \geq 1\}$, and

(b) $\mathcal{F}^S = \mathcal{F}_W^S$ for $\delta_1$ sufficiently small and $M_1$ sufficiently large in the definition of $\mathcal{F}_W^S$.

The proof of Lemma 31.9 follows the same lines as the proof of Lemma 27.4. As in (27.73), we have

\[
\tilde{V}_n(\theta, \beta_n) = E_F f_i f_i' - (E_F f_i)(E_F f_i)' + o_p(1)
\]

(31.32)
and

\[
\hat{R}_n(\theta_0, \hat{\beta}_n) = (B' \otimes I_k) (E_{F_n} f_i f_i' - (E_{F_n} f_i)(E_{F_n} f_i')) (B \otimes I_k) + o_p(1) \\
\rightarrow_p R_h := (B' \otimes I_k) [h_n - vec((0^k, h_4))vec((0^k, h_4))^\prime] (B \otimes I_k),
\]

where the convergence holds by results stated (or proved exactly as) in the proof of Lemma 31.5(b) below. This implies that Assumption WU$^S$(a) holds, namely, $\hat{U}_{2n} - U_{2F_{wn}} = (\hat{\Omega}_{wn}(\theta_0, \hat{\beta}_n), \hat{R}_{wn}(\theta_0, \hat{\beta}_n)) - (\Omega_{F_{wn}}, R_{F_{wn}}) = o_p(1)$. Assumption WU$^S$(b) holds by the same argument as the one for the full vector case that starts in the paragraph containing (27.77). This establishes Lemma 31.9(b).

Lemma 31.9(b) holds by the same argument as the one for the full vector case that starts after the paragraph that contains (27.77).

### 31.2 Proof of Lemma 31.5

Throughout the proof we use the shorthand notation $g_i(\beta) = g_i(\theta_0, \beta)$ and $\hat{g}_n(\beta) = n^{-1} \sum_{i=1}^n g_i(\theta_0, \beta)$ and write $g_i$ for $g_i(\beta^*)$, where $\beta^*$ is the true value of $\beta$, and analogously for other expressions, e.g., we write $\hat{D}_n(\beta)$ for $\hat{D}_n(\theta_0, \beta)$ and $G_i$ for $G_i(\theta_0, \beta^*)$. Furthermore, to simplify notation, we replace subscripts $F_n$ by $n$, e.g., we write $E_n$ rather than $E_{F_n}$.

**Proof of Lemma 31.5(a).** Given $\lambda_{n,h}^S : n \geq 1$, let $F_n$ and $\beta_n^*$ denote the distribution of $W_i$ and the true parameter $\beta$ when the sample size is $n$. Let $\bar{Q}_n(\beta) = ||\hat{g}_n(\beta)||^2$ and $Q_n(\beta) = ||E_n g_i(\beta)||^2$, where a subscript $n$ on $E$ or $P$ denotes expectation or probability under $F_n$, respectively. The following proof adapts the standard proof for consistency of extremum estimators to the case of drifting DGP’s $\{\lambda_{n,h}^S : n \geq 1\}$.

**a1.** We first show consistency of the first-step estimator, i.e., $\beta_n^* \rightarrow_p 0^0$ under $\lambda_{n,h}^S : n \geq 1$. Let $\varepsilon > 0$. By the identifiability condition in $\mathcal{F}_{AR,1}^S$ in (9.14), there exists $\delta_\varepsilon > 0$ such that $\beta \in B \setminus B(\beta_n^*, \varepsilon)$ implies $Q_n(\beta) \geq \delta_\varepsilon$. Thus,

\[
P_n(||\beta_n - \beta_n^*|| > \varepsilon) = P_n(\beta_n \in B \setminus B(\beta_n^*, \varepsilon)) \\
\leq P_n(Q_n(\beta_n) - \bar{Q}_n(\beta_n) + \bar{Q}_n(\beta_n) \geq \delta_\varepsilon) \\
\leq P_n(Q_n(\beta_n) - \bar{Q}_n(\beta_n) + \bar{Q}_n(\beta_n) \geq \delta_\varepsilon) \\
\leq P_n(2 \sup_{\beta \in B} |Q_n(\beta) - \bar{Q}_n(\beta)| \geq \delta_\varepsilon) \\
\rightarrow 0,
\]
where the second inequality holds because \( \hat{Q}_n(\cdot) \) is minimized by \( \tilde{\beta}_n \), the third inequality holds because \( Q_n(\beta^*_n) = 0 \), and the convergence result holds, because, as we show now, \( \sup_{\beta \in B} |\hat{Q}_n(\beta) - Q_n(\beta)| \to_p 0 \).

For \( \delta > 0 \), define
\[
Y_{i\delta} := \sup_{\beta \in B} \sup_{\beta' \in B(\beta, \delta)} ||g_i(\beta') - g_i(\beta)||,
\]
whose distribution depends on \( F_n \). By Assumption gB, \( g_i(\cdot) \) is uniformly continuous on \( B \) and therefore \( Y_{i\delta} \to 0 \) a.s. \( [\mu] \) as \( \delta \to 0 \). Furthermore, \( E_\mu Y_{i\delta} \leq 2 E_\mu \sup_{\beta \in B} ||g_i(\beta)|| < \infty \), where the latter inequality holds by the conditions in \( \mathcal{F}^S_{AR,1} \). Therefore, by the dominated convergence theorem (DCT) it follows that \( E_\mu Y_{i\delta} \to 0 \) as \( \delta \to 0 \). Let \( f_n \) denote the Radon-Nikodym derivative of \( F_n \) wrt \( \mu \) and note that by assumption \( f_n \leq M \). We have \( \sup_n E_n Y_{i\delta} = \sup_n E_\mu f_n Y_{i\delta} \leq E_\mu M Y_{i\delta} \to 0 \) as \( \delta \to 0 \).

By Assumption gB, \( B \) is compact. Therefore, for \( \delta > 0 \) there is a finite cover of \( B \) by balls of radius \( \delta \) centered at some points \( \beta_j, j = 1, \ldots, J_\delta \), i.e., \( B \subset \bigcup_{j=1}^{J_\delta} B(\beta_j, \delta) \). Let
\[
H_n(\beta) = \tilde{g}_n(\beta) - E_n g_i(\beta).
\]
Because \( \mathcal{F}^S_{AR,1} \) imposes \( \sup_{\beta \in B} E_F ||g_i(\beta)||^{1+\gamma} \leq M \), a Lyapunov-type WLLN implies that for any fixed \( \beta \in B \) we have \( H_n(\beta) \to_p 0^k \) as \( n \to \infty \). It then follows that for \( \varepsilon > 0 \) we have
\[
P_n(\sup_{\beta \in B} ||H_n(\beta)|| > 2\varepsilon)
\leq P_n(\max_{j=1,\ldots,J_\delta} \sup_{\beta \in B(\beta_j, \delta)} ||H_n(\beta) - H_n(\beta_j)|| + ||H_n(\beta_j)|| > 2\varepsilon)
\leq P_n(\sup_{\beta \in B} \sup_{\beta' \in B(\beta, \delta)} ||H_n(\beta') - H_n(\beta)|| > \varepsilon) + P_n(\max_{j=1,\ldots,J_\delta} ||H_n(\beta_j)|| > \varepsilon),
\]
where the first inequality holds by the triangle inequality.

For the first summand in (31.36), we have the following bound
\[
P_n(\sup_{\beta \in B} \sup_{\beta' \in B(\beta, \delta)} ||H_n(\beta') - H_n(\beta)|| > \varepsilon)
\leq P_n\left(\frac{1}{n} \sum_{i=1}^{n} (Y_{i\delta} + E_n Y_{i\delta}) > \varepsilon\right)
\leq E_n \frac{1}{n} \sum_{i=1}^{n} (Y_{i\delta} + E_n Y_{i\delta}) / \varepsilon
= 2E_n Y_{i\delta} / \varepsilon,
\]
where the first inequality holds by the triangle inequality and the second inequality holds by
Markov’s inequality. Because, as shown above, \( \sup_n E_n Y_{i\delta} \to 0 \) as \( \delta \to 0 \), for given \( \nu > 0 \) there is \( \delta_\nu > 0 \) such that \( 2E_n Y_{i\delta}/\varepsilon < \nu/2 \) for all \( n \) and for all \( \delta \leq \delta_\nu \). Because \( H_n(\beta) \to_p 0 \) we can find a finite \( n_{\delta_\nu} \in N \) such that for all \( n \geq n_{\delta_\nu} \) we have \( P_n(\max_j \| H_n(\beta_j) \| > \varepsilon) < \nu/2 \). This proves

\[
P_n(\sup_{\beta \in B} ||H_n(\beta)|| > 2\varepsilon) \to 0 \tag{31.38}
\]
as \( n \to \infty \). By the reverse triangle inequality, we then obtain the desired \( \sup_{\beta \in B} |\bar{Q}_n(\beta) - Q_n(\beta)| \to_p 0 \) as \( n \to \infty \).

(a2). Next, we show consistency of \( \tilde{\beta}_n \). Let \( \{\beta_n - \beta_n^*: n \geq 1\} \) be any nonstochastic sequence that converges to \( 0^b \). We can write \( E_n g_i(\beta_n) - E_n g_i(\beta_n^*) = E_n h_n \) for \( h_n = (g_i(\beta_n) - g_i(\beta_n^*))f_n \). Because \( f_n \leq M \) and \( g_i(\cdot) \) is uniformly continuous on \( B \) by Assumption gB, it follows that \( h_n \to 0^k \) a.s.\([\mu] \). Furthermore, \( E_n h_n \leq 2ME_n \sup_{\beta \in B} ||g_i(\beta)|| < \infty \) by the conditions in \( F_{AR}^S \). Therefore, by the DCT, \( E_n h_n \to 0^k \).

Define \( E_n g_i(\tilde{\beta}_n) = E_n g_i(\beta)|_{\beta = \tilde{\beta}_n} \). That is, the expectation is taken first treating \( \beta \) as nonrandom, and then the resulting expression is evaluated at the random vector \( \tilde{\beta}_n \). For any given \( \varepsilon > 0 \),

\[
||\hat{g}_n(\tilde{\beta}_n)|| \leq ||\hat{g}_n(\tilde{\beta}_n) - E_n g_i(\tilde{\beta}_n)|| + ||E_n g_i(\tilde{\beta}_n) - E_n g_i(\beta_n^*)|| \\
\leq \sup_{\beta \in B(\beta_n^*, \varepsilon)} ||\hat{g}_n(\beta) - E_n g_i(\beta)|| + o_p(1) \\
= o_p(1), \tag{31.39}
\]

where the first inequality holds by the triangle inequality, the second inequality holds wp \( \to 1 \) because \( \beta_n - \beta_n^* \to_p 0^b \) and \( E_n h_n \to 0^k \), and the equality holds by \( (31.38) \).

Furthermore, \( n^{-1} \sum_{i=1}^n g_i(\tilde{\beta}_n)g_i(\beta_n^*) = E_n g_i(\beta_n^*) ) \to_p 0^{k \times k} \). This result is proved as in \( (31.39) \), by establishing a UWLLN on \( B(\beta_n^*, \varepsilon) \) for \( n^{-1} \sum_{i=1}^n g_i(\cdot)g_i(\cdot)^* \) and by showing that \( E_n h_n \to 0^{k \times k} \) for \( h_n = (g_i(\beta_n)g_i(\beta_n^*) - g_i(\beta_n^*)g_i(\beta_n^*)^*)^*f_n \) when \( \beta_n - \beta_n^* \) converges to \( 0^b \). The latter follows as above from the DCT using \( E_n \sup_{\beta \in B(\beta_n^*, \varepsilon)} ||g_i(\beta)||^2 < \infty \) by the conditions in \( F_{AR}^S \). The former follows using the same proof as for \( (31.38) \) noting that by the conditions in \( F_{AR}^S \) we have \( E_n \sup_{\beta \in B(\beta_n^*, \varepsilon)} ||g_i(\beta)||^2 < \infty \) and \( \sup_{\beta \in B(\beta_n^*, \varepsilon)} E_F ||g_i(\beta)||^{2+\gamma} \) is uniformly bounded. We have therefore shown that \( (\varphi_n^* \varphi_n)^{-1} - E_n g_i g_i^\prime \to_p 0^{k \times k} \), where \( \varphi_n^* \varphi_n \) is defined in \( (9.6) \). Because \( F_{AR}^S \) imposes \( \lambda_{\min}(E_F g_i g_i^\prime) \geq \delta \), it follows that

\[
\varphi_n^* \varphi_n - (E_n g_i g_i^\prime)^{-1} \to_p 0^{k \times k} \tag{31.40}
\]

The remainder of the consistency proof is analogous to the proof in part (a1), but with \( \bar{Q}_n(\beta) := \)
\[ \| \hat{\varphi}_n \hat{g}_n (\beta) \|^2 \text{ and } Q_n (\beta) := \| (E_n g_i g_i')^{-1/2} E_n g_i (\beta) \|^2. \]

To establish a UWLLN for \( \hat{Q}_n (\beta) \), note that

\[
\sup_{\beta \in B(\beta^* \pm \epsilon)} \| \hat{\varphi}_n \hat{g}_n (\beta) - (E_n g_i g_i')^{-1/2} E_n g_i (\beta) \| \\
\leq \| \hat{\varphi}_n \| \sup_{\beta \in B(\beta^*)} \| \hat{g}_n (\beta) - E_n g_i (\beta) \| + \| \hat{\varphi}_n - (E_n g_i g_i')^{-1/2} \| \sup_{\beta \in B(\beta^* \pm \epsilon)} \| E_n g_i (\beta) \| \\
= o_p (1), \tag{31.41}
\]

where the inequality uses the triangle inequality and the equality uses \( \| \hat{\varphi}_n \| = O(1) \) because \( \lambda_{\min} (E_n g_i g_i') \geq \delta \). Equation \( \tag{31.41} \) implies that \( \sup_{\beta \in B(\beta^* \pm \epsilon)} | \hat{Q}_n (\beta) - Q_n (\beta) | = o_p (1) \).

**a3**. Now, we derive the limiting distribution of \( \hat{\beta}_n \) under \( \{ \lambda_{n, n}^S : n \geq 1 \} \). As above, \( \hat{Q}_n (\beta) := \| \hat{\varphi}_n \hat{g}_n (\beta) \|^2 \). Because \( \beta^* \) is bounded away from the boundary of \( B \), \( \hat{\beta}_n - \beta^* \to_p 0^b \), and \( g_i (\cdot) \in C^2(B(\beta^*, \vartheta)) \), the following FOC holds wp \( \to 1 \) and element-by-element mean-value expansions of \( \frac{\partial}{\partial \beta} Q_n (\hat{\beta}_n) \) exist:

\[
0^b = \frac{\partial}{\partial \beta} Q_n (\hat{\beta}_n) = \frac{\partial}{\partial \beta} Q_n (\beta^*) + \frac{\partial^2}{\partial \beta \partial \beta} Q_n (\beta^*) (\hat{\beta}_n - \beta^*), \tag{31.42}
\]

where the mean-value \( \beta^+_m \) lies on the segment joining \( \hat{\beta}_n \) and \( \beta^* \) (and hence satisfies \( \hat{\beta}_n - \beta^* \to_p 0^b \)).

For \( m, j = 1, \ldots, b \), we have

\[
\frac{\partial}{\partial \beta} Q_n (\beta) = \left[ n^{-1} \sum_{i=1}^n \frac{\partial}{\partial \beta} g_i (\beta) \right] \hat{\varphi}_n \hat{g}_n n^{-1} \sum_{i=1}^n g_i (\beta) \text{ and}
\]

\[
\left[ \frac{\partial^2}{\partial \beta \partial \beta} Q_n (\beta) \right]_{m,j} = n^{-1} \sum_{i=1}^n \frac{\partial}{\partial \beta_m} g_i (\beta) \hat{\varphi}_n \hat{g}_n n^{-1} \sum_{i=1}^n \frac{\partial}{\partial \beta_j} g_i (\beta)
\]

\[ + n^{-1} \sum_{i=1}^n \frac{\partial^2}{\partial \beta_m \partial \beta_j} g_i (\beta) \hat{\varphi}_n \hat{g}_n n^{-1} \sum_{i=1}^n g_i (\beta). \tag{31.43} \]

By the argument in \( \tag{31.39} \), \( n^{-1} \sum_{i=1}^n g_i (\beta^+_m) \to_p 0^k \) under \( \{ \lambda_{n, n}^S : n \geq 1 \} \). Furthermore,

\[
n^{-1} \sum_{i=1}^n \frac{\partial}{\partial \beta_j} g_i (\beta^+_n) = E_n \frac{\partial}{\partial \beta_j} g_i \to_p 0^k \tag{31.44}
\]

under \( \{ \lambda_{n, n}^S : n \geq 1 \} \). The latter holds by the argument in \( \tag{31.39} \) with \( g_i (\hat{\beta}_n) \) replaced by \( \frac{\partial}{\partial \beta_j} g_i (\beta^+_n) \) and using the assumptions \( \sup_{\beta \in B(\beta^*, \vartheta)} E_n \| G_{ij} (\beta) \|^2 \to_p 0^k \) and \( E_n \sup_{\beta \in B(\beta^*, \vartheta)} \| G_{ij} (\beta) \| \) are uniformly bounded in \( F^S \). In addition, \( n^{-1} \sum_{i=1}^n \frac{\partial^2}{\partial \beta_m \partial \beta_j} g_i (\beta^+_n) = O_p (1) \) (again by an argument as in \( \tag{31.39} \)) with \( g_i (\hat{\beta}_n) \) replaced by \( \frac{\partial^2}{\partial \beta_m \partial \beta_j} g_i (\beta^+_n) \) and using the fact that \( \sup_{\beta \in B(\beta^*, \vartheta)} E_n \| \frac{\partial^2}{\partial \beta_m \partial \beta_j} g_i (\beta) \|^2 \to_p 0^k \) and \( E_n \sup_{\beta \in B(\beta^*, \vartheta)} \| \frac{\partial^2}{\partial \beta_m \partial \beta_j} g_i (\beta) \| \) are uniformly bounded by the conditions in \( F^S \). It follows that \( \frac{\partial^2}{\partial \beta \partial \beta} Q_n (\beta^+_n) - B^* \to_p 0^b \times b \) under \( \{ \lambda_{n, n}^S : n \geq 1 \} \), where \( B^* :=

139
$E_n G_{i\beta}' (E_n g_i g_i')^{-1} E_n G_{i\beta}$.

Because $\lambda_{\min}(B_n^\ast)$ is bounded away from zero (since $\tau_{\min}(E_n G_{i\beta}) \geq \delta$ for $F_n \in \mathcal{F}^S$), it follows that $\frac{\partial^2}{\partial \beta \partial \beta'} Q_n(\beta_n^\ast)$ is invertible wp→ 1. This and (31.42) give

$$n^{1/2}(\tilde{\beta}_n - \beta_n^\ast) = -(B_n^\ast + o_p(1))^{-1} \sqrt{n} \frac{\partial}{\partial \beta} Q_n(\beta_n^\ast).$$

(31.45)

From above, we have

$$n^{1/2} \frac{\partial}{\partial \beta} Q_n(\beta_n^\ast) = (E_n G_{i\beta})'(E_n g_i g_i')^{-1} n^{-1/2} \sum_{i=1}^n g_i(\beta_n^\ast) + o_p(1).$$

(31.46)

By the CLT result in (31.20), $n^{-1/2} \sum_{i=1}^n g_i(\beta_n^\ast) \rightarrow_d \mathbf{g}_h$. Combining the previous results and using the definition of the vector $h$, we obtain the result of Lemma 31.5(a). \qed

**Proof of Lemma 31.5(b).** Using Lemma 31.5(a) or the same argument employed multiple times in the proof of Lemma 31.3(a), we have: $n^{-1} \sum_{i=1}^n g_i(\tilde{\beta}_n) \rightarrow_p 0$, $n^{-1} \sum_{i=1}^n g_i(\tilde{\beta}_n) g_{ij}(\tilde{\beta}_n) - E_n g_i g_{ij} \rightarrow_p 0$, $n^{-1} \sum_{i=1}^n g_i(\tilde{\beta}_n) g_{ij}(\tilde{\beta}_n) g_{ij}(\tilde{\beta}_n) - \lambda_{S,3,j,n}^S \rightarrow_p 0$, $\tilde{\Omega}_n(\tilde{\beta}_n) - (E_n g_i g_i) \rightarrow_p 0$, $E_n G_{i\beta} - E_n G_{i\beta} \rightarrow_p 0$, and $n^{-1} \sum_{i=1}^n G_{i\beta}(\tilde{\beta}_n) - \lambda_{S,3,j,n}^S \rightarrow_p 0$. Therefore, $\tilde{\Omega}_n(\tilde{\beta}_n) \rightarrow_p h_{5,g}^S$, $G_{\beta_n}(\tilde{\beta}_n) \rightarrow_p h_{4,\beta}$, and $\tilde{J}_n(\tilde{\beta}_n) \rightarrow_p h_{5,\beta}^{-1/2} h_{4,\beta}$. \qed

**Proof of Lemma 31.5(c).** We derive the limit distributions of (i) $\tilde{g}_n(\tilde{\beta}_n)$, (ii) $\tilde{D}_n(\tilde{\beta}_n) - E_n G_{i\beta}$, (iii) $\tilde{\Omega}_n(\theta_0, \tilde{\beta}_n) - E_n g_i g_i'$, and (iv) $\tilde{G}_{\beta_n}(\theta_0, \tilde{\beta}_n) - E_n G_{i\beta}$ under $\{\lambda_{n,h}^S : n \geq 1\}$ in (c1)-(c4) below, respectively.

(c1). We have

$$n^{1/2} \tilde{g}_n(\tilde{\beta}_n) = n^{1/2} \tilde{g}_n(\beta_n^\ast) + \tilde{G}_{\beta_n}(\beta_n^\ast) n^{1/2}(\tilde{\beta}_n - \beta_n^\ast)$$

$$= (I_k - (E_n G_{i\beta}) B_n^\ast (E_n G_{i\beta})'(E_n g_i g_i')^{-1}) n^{1/2} \tilde{g}_n(\beta_n^\ast) + o_p(1),$$

(31.47)

where the first equality uses a mean-value expansion with $\beta_n^\ast$ on the segment joining $\tilde{\beta}_n$ and $\beta_n^\ast$ and the second equality holds by (31.45) and (31.46). Therefore,

$$n^{1/2} \tilde{g}_n(\tilde{\beta}_n) \rightarrow_d \tilde{g}_h^S := h_{5,g}^S M_{h_{5,g}^S h_{4,\beta}} h_{5,g}^{-1/2} \tilde{g}_h.$$

(31.48)

Note that the assumption of strong identification of $\beta$, namely $\tau_{\min}(E_F G_{i\beta}) \geq \delta$ in $\mathcal{F}^S$, implies that $h_{4,\beta}$ has full column rank $b$.

(c2). Recall the definition of $\tilde{\Gamma}_{jn}(\cdot)$ for $j = 1, \ldots, p$ in (5.2). Under sequences $\{\lambda_{n,h}^S : n \geq 1\}$, we
have

\[
(\hat{\Gamma}'_{n}(\hat{\beta}_{n}), \ldots, \hat{\Gamma}'_{m}(\hat{\beta}_{n}))(\hat{\Omega}^{-1}_{n}(\hat{\beta}_{n}) - ((E_{n}G_{11}g'_{1}), \ldots, (E_{n}G_{ip}g'_{p}))(\Omega^{-1}_{n} \to_{p} 0), \tag{31.49}
\]

which is established analogously to the results in (31.40) and (31.44), using the uniform finite bounds on \(\sup_{\beta \in B(\beta^*_n, \theta)} E_{n}||(\frac{\partial}{\partial \theta \beta^*_n} g_{i}(\beta) )g_{ij}(\beta)||^{1+\gamma}\) and \(E_{n} \sup_{\beta \in B(\beta^*_n, \theta)} ||(\frac{\partial^{2}}{\partial \theta \beta^*_n \partial \beta} g_{i}(\beta))g_{ij}(\beta)||\) for \(j = 1, \ldots, k\) in \(\mathcal{F}_{S}\).

Using \(g_{i}(\cdot) \in C^{2}(B(\beta^*, \theta))\), by a second-order Taylor expansion of \(\tilde{g}_{n}(\hat{\beta}_{n})\) about \(\beta^*_n\) and a mean-value expansion of \(G_{i}(\hat{\beta}_{n})\) (as in (31.47), we obtain

\[
n^{1/2}vec(\tilde{D}_{n}(\hat{\beta}_{n}) - D_{n}) = \sum_{i=1}^{n} vec(G_{i} - E_{n}G_{i}) - \begin{pmatrix}
E_{n}G_{i1}g'_{1} \\
\vdots \\
E_{n}G_{ip}g'_{p}
\end{pmatrix} \Omega^{-1}_{n}g_{i} + vec((E_{n}G_{i\theta j}g_{ij})(n^{1/2}(\hat{\beta}_{n} - \beta^*_n), \ldots, (E_{n}G_{i\theta p}g_{ij})(n^{1/2}(\hat{\beta}_{n} - \beta^*_n)))
- \begin{pmatrix}
E_{n}G_{i1}g'_{1} \\
\vdots \\
E_{n}G_{ip}g'_{p}
\end{pmatrix} \Omega^{-1}_{n}g_{i} \tag{31.50}
\]

where \(E_{n}G_{ij}g'_{\ell} = E_{n}G_{ij}g'_{\ell}\) for any observation indices \(\ell, i \geq 1\) by stationarity. The terms on the rhs of the first line of (31.50) consist of the term \(D_{n} = E_{n}G_{i}\) and the first term of the expansions of \(G_{i}(\hat{\beta}_{n})\) and \(g_{i}(\hat{\beta}_{n})\), respectively, replacing sample averages by expectations as in (31.49). The term in the second line comes from the second term of the expansion of \(G_{i}(\hat{\beta}_{n})\). For this, we use

\[
\tilde{G}_{\theta j, \beta n}(\beta^*_n) - E_{n}G_{i\theta j} \rightarrow_{p} 0^{k \times b} \text{ for } j = 1, \ldots, p \tag{31.51}
\]

for any sequence \(\beta^*_n\) such that \(\beta^*_n - \beta^* \rightarrow_{p} 0\). The latter is established (as in several places above) using the assumptions that \(\sup_{\beta \in B(\beta^*_n, \theta)} E_{n}||(\frac{\partial^{2}}{\partial \theta \beta^*_n \partial \theta^*} g_{i}(\beta) ||^{1+\gamma}\) and \(E_{n} \sup_{\beta \in B(\beta^*_n, \theta)} ||(\frac{\partial^{2}}{\partial \theta \beta^*_n \partial \beta} g_{i}(\beta))g_{ij}(\beta)||\) are uniformly bounded in \(\mathcal{F}_{S}\). The first term of the third line comes from the second term of the expansion of \(g_{i}(\hat{\beta}_{n})\) and using (31.44) and (31.49). The \(o_{p}(1)\) term contains the errors caused by the approximations in (31.49) and (31.51) and from the third term of the expansion of \(g_{i}(\hat{\beta}_{n})\) (which is indeed \(o_{p}(1)\) given the moment bounds in \(\mathcal{F}_{S}\) on \(\frac{\partial^{2}}{\partial \theta \beta^*_n \partial \beta} g_{i}(\beta)\)).

Equation (31.50), combined with Lemma (31.5a), (31.20), (31.14), and the paragraph containing (31.16), give

\[
n^{1/2}vec(\tilde{D}_{n}(\hat{\beta}_{n}) - D_{n}) \rightarrow_{d} vec(\tilde{D}_{h}^{S}) := (vec(\tilde{G}_{h}) - h_{5, G_{g}h^{-1}_{5, g} \tilde{G}_{h}} + vec(h_{4, \theta_1, \beta^*_{h}}, \ldots, h_{4, \theta_p, \beta^*_{h}}) - h_{5, G_{g}h^{-1}_{5, g} h_{4, \beta^*_{h}}} \tag{31.52}
\]
Note that $\vec{y}^S_h$ and $\vec{\beta}_h$ are independent because

$$\text{cov}(M_{h, g, \beta}^{-1/2}h_{g, \beta}^{-1/2} \vec{y}_h, \vec{\beta}_h) = M_{h, g, \beta}^{-1/2}h_{g, \beta}^{-1/2}(h_{g, \beta}^{-1/2}h_{g, \beta})^l(h_{g, \beta}^{-1/2}h_{g, \beta})^{-1} = 0^{k \times h}. \quad (31.53)$$

Next, we establish that $\vec{y}^S_h$ and $\vec{D}^S_h$ (defined in [31.21]) are independent. The last two summands that make up $\vec{D}^S_h$ are independent of $\vec{y}^S_h$ because $\vec{y}^S_h$ and $\vec{\beta}_h$ are independent. Regarding the first summand, recall that from (31.20) we know that $\text{vec}(G_h)$ and $\vec{y}_h$ are jointly normally distributed and because $\text{cov}(\vec{y}_h, \text{vec}(G_h) - h_{5, G, \beta}^{-1} \vec{y}_h) = 0^{k \times pk}$, it follows that $\text{vec}(G_h) - h_{5, G, \beta}^{-1} \vec{y}_h$ and $\vec{y}^S_h$ are independent.

(c3). Next we derive the asymptotic distribution of $\hat{\Omega}_n(\hat{\beta}_n)$. Let $j \in \{1, ..., k\}$. By a mean-value expansion, for some vectors $\beta^*_{n}$ and $\beta^+_{n}$ on the line segment joining $\hat{\beta}_n$ and $\beta^*_n$, under $\{\lambda_{n,h} \in \Lambda^S : n \geq 1\}$, we have

$$n^{1/2} \left[ \hat{\Omega}_{jn}(\hat{\beta}_n) - \Omega_{jn} \right] = n^{1/2} \left[ -\sum_{i=1}^{n} g_i g_{ij} - \Omega_{jn} \right] + n^{-1} \sum_{i=1}^{n} \left[ G_{i\beta}(\beta^*_n) g_{ij}(\beta^*_n) + g_i(\beta^*_n)^{(j)} \partial g_{ij}(\beta^*_n) \right] n^{1/2}(\hat{\beta}_n - \beta^*_n)$$

$$- \Phi_{jn}(\hat{\beta}_n) \hat{\Omega}_n^{-1}(\hat{\beta}_n) \left[ n^{1/2}(\vec{g}_n) + G_{i\beta}(\beta^*_n) n^{1/2}(\vec{\beta}_n - \beta^*_n) \right] + o_p(1)$$

$$\rightarrow_d \mathcal{X}^S_{h,j} := T_{j,h,3} - h_{5,3,j} h_{5, g, \beta}^{-1} \vec{y}_h$$

$$+ [(h_{5, \beta_{1,j}}, ..., h_{5, \beta_{j,j}}) - (h_{5, \beta_{1,j}}', ..., (h_{5, \beta_{j,j}}')' - h_{5,3,j} h_{5, g, \beta}) \vec{\beta}_h], \quad (31.54)$$

where $T_{j,h,3} \in \mathbb{R}^k$ denotes the $(j - 1)k + 1, ..., jk$ components of $T_{h,3}$, $(h_{5, \beta})_j' \in \mathbb{R}^k$ denotes the $j$-th column of $(h_{5, \beta})_j' \in \mathbb{R}^{l \times k}$ for $l = 1, ..., b$, and the convergence result holds by the moment restrictions in the parameter space, WLLN’s, (31.20), and part (a) of the lemma. Equation (31.54) yields $n^{1/2}(\hat{\Omega}_n(\hat{\beta}_n) - \Omega_{jn}) \rightarrow_d \mathcal{X}^S_h := (\mathcal{X}^S_{h,1}, ..., \mathcal{X}^S_{h,k})$.

By definition, $\mathcal{X}^S_{h,j}$ is a nonrandom function of $T_{j,h,3} - h_{5,3,j} h_{5, g, \beta}^{-1} \vec{y}_h$ and $\vec{\beta}_h$. By (31.55), $\vec{\beta}_h$ and $\vec{g}^S_h$ are independent. In addition, $T_{j,h,3} - h_{5,3,j} h_{5, g, \beta}^{-1} \vec{y}_h$ and $\vec{g}_h$ are independent, because they are jointly normal with a zero covariance matrix. Therefore, $T_{j,h,3} - h_{5,3,j} h_{5, g, \beta}^{-1} \vec{y}_h$ and $\vec{g}^S_h := h_{5, g, \beta}^{1/2} M_{h, g, \beta}^{-1/2} h_{5, g, \beta}^{-1/2} \vec{y}_h$ are independent. This shows that $\mathcal{X}^S_h := (\mathcal{X}^S_{h,1}, ..., \mathcal{X}^S_{h,k})$ and $\vec{g}^S_h$ are independent.

Equation (31.54) yields $n^{1/2}(\hat{\Omega}_{jn}(\hat{\beta}_n) - \Omega_{jn}) \rightarrow_d \mathcal{X}^S_h$, as desired.
(c4). As in (31.54), for \(j \in \{1, \ldots, b\}\), under \(\{\lambda_{n,h}^S \in \Lambda^S : n \geq 1\}\), we have

\[
n^{1/2} \left[ \bar{G}_{j,n}(\bar{\beta}_n) - E_n G_{i\beta_j} \right] \\
= n^{1/2} \left[ -n^{-1} \sum_{i=1}^{n} G_{i\beta_j,n} - E_n G_{i\beta_j} \right] + n^{-1} \sum_{i=1}^{n} G_{i\beta_j,\beta} (\beta_n^+ n^{1/2} (\beta_n - \beta_n^*) \\
- \bar{F}_{jn}(\bar{\beta}_n) \bar{\Omega}_n(\bar{\beta}_n)^{-1} \left[ n^{1/2} \bar{g}_n + G_{i\beta}(\beta_n^+) n^{1/2} (\beta_n - \beta_n^*) \right] \\
\to_d \bar{\varphi}_{h,j} = T_{j,h,4} - h_{5,j} h_{5,g} \bar{g}_h + (h_{4,\beta,j} - h_{5,j} h_{5,g} h_{4,\beta}) \bar{\beta}_h,
\]

(31.55)

where \(T_{j,h,4} \in \mathbb{R}^k\) denotes the \((j - 1)k + 1, \ldots, jk\) components of \(T_{h,4}\). Equation (31.55) and \(\bar{\varphi}_h^S := (\bar{\varphi}_{h,1}, \ldots, \bar{\varphi}_{h,b})\) yield \(n^{1/2} \left[ \bar{G}_{\beta,n}(\bar{\beta}_n) - E_n G_{i\beta_j} \right] \to_d \bar{\varphi}_h^S\), as desired.

By the same argument as for \(\bar{\varphi}_h^S\) above, \(\bar{\varphi}_h := (\bar{\varphi}_{h,1}, \ldots, \bar{\varphi}_{h,b})\) and \(\bar{\varphi}_h^S\) are independent. \(\square\)

**Proof of Lemma 31.5(d).** First, we obtain the asymptotic distributions of \(\bar{\Omega}_n^{-1/2}(\bar{\beta}_n), \bar{J}_n(\bar{\beta}_n),\) and \(\tilde{O}_n = \tilde{O}_n(\tilde{J}_n(\bar{\beta}_n))\).

Consider the function that maps \(vec(\varphi)\) onto \(vec(\varphi^{-1/2})\), where \(\varphi \in \mathbb{R}^{k \times k}\) is positive definite. Denote by \(\bar{\varphi}_h \in \mathbb{R}^{k^2 \times k^2}\) the matrix of partial derivatives of that mapping evaluated at \(vec(h_{5,g})\). By \(n^{1/2}(\bar{\Omega}_{jn}(\bar{\beta}_n) - \Omega_{jn}) \to_d \bar{\varphi}_h^S\), which holds by part (c) of the lemma (and is proved in (31.54)), and the delta method, we have

\[
n^{1/2} \left[ \bar{\Omega}_n^{-1/2}(\bar{\beta}_n) - \Omega_n^{-1/2} \right] \to_d vec^{-1}_{k,k}(\bar{\varphi}_h vec(\bar{\varphi}_h^S)).
\]

(31.56)

The asymptotic distribution \(\bar{J}_n(\bar{\beta}_n) := \bar{\Omega}_n^{-1/2}(\bar{\beta}_n) G_{\beta,n}(\bar{\beta}_n)\) is obtained as follows:

\[
n^{1/2} \left[ \bar{J}_n(\bar{\beta}_n) - \Omega_n^{-1/2} E_n G_{\beta_i} \right] \\
= \bar{\Omega}_n^{-1/2}(\bar{\beta}_n) n^{1/2} \left[ G_{\beta,n}(\bar{\beta}_n) - E_n G_{\beta_i} \right] + n^{1/2} \left[ \bar{\Omega}_n^{-1/2}(\bar{\beta}_n) - \Omega_n^{-1/2} \right] E_n G_{\beta_i} \\
\to_d \bar{\varphi}_h^S := h_{5,g}^{-1/2} \bar{\varphi}_h + vec^{-1}_{k,k}(\bar{\varphi}_h vec(\bar{\varphi}_h^S)) h_{4,\beta},
\]

(31.57)

where the convergence uses (31.56) and \(n^{1/2}(\bar{G}_{\beta,n}(\bar{\beta}_n) - E_n G_{i\beta_j}) \to_d \bar{\varphi}_h^S\), which holds by part (c) of the lemma (and is proved in (31.55)).

Assume wlog that the first \(b\) columns of \((h_{5,g}^{-1/2} h_{4,\beta})'\) are linearly independent.\(^{75}\) Then, by (31.4) and (31.5), we have

\[
O_n = O(J_n) = (\left( -j_{n(1)}' (J_n)_{1}^{-1}, e_1', \ldots, (j'_{n(k-b)} (J_n)_{1}^{-1}, e'_{k-b}) \right) and \ \ \\
\tilde{O}_n = O(\tilde{J}_n) = (\left( -j'_{n(1)} (\bar{J}_n)_{1}^{-1}, e_1', \ldots, (j'_{n(k-b)} (\bar{J}_n)_{1}^{-1}, e'_{k-b}) \right),
\]

(31.58)

\(^{75}\)If the first \(b\) columns of \((h_{5,g}^{-1/2} h_{4,\beta})'\) are linearly dependent, \(O_n\) and \(\tilde{O}_n\) are given by analogous formulas involving \(R_n' = E_n G_{i\beta} \Omega_n^{-1/2} = (R_{n1}', R_{n2}')\) and \(R_n(\bar{\beta}_n)' = (R_{n1}', R_{n2}')\) just based on a different set of \(b\) columns of \((h_{5,g}^{-1/2} h_{4,\beta})'\).
where again $J' = (J'_{11}, J'_{n2})$ with $J'_{11} \in R^{b \times b}$ and $J'_{n2} = (j_{n1}, \ldots, j_{nk-b}) \in R^{b \times (k-b)}$, $j_{nl} \in R^b$ for $l = 1, \ldots, k-b$, and analogously for $J'_n$. Consider the function that maps $vec(J)$ for $J \in R^{k \times b}$ onto $vec(O(J)) \in R^{b(k-b)}$, where $O(J)$ is defined by (31.4) and (31.5). Denote by $\overline{B}_h \in R^{b(k-b) \times kb}$ the matrix of partial derivatives of that mapping evaluated at $vec(h_{n, q}^{-1/2} h_{4, \beta})$. Then, by the delta method,

$$n^{1/2}(\bar{O}_n - O_n) \rightarrow_d vec^{-1}_{k, k-b}(\overline{B}_h vec(\overline{S}_h^S)) \quad (31.59)$$

and the asymptotic distribution is independent of $\overline{S}_h^S$.

Given the asymptotic distributions of $\tilde{\Omega}_n^{-1/2}(\beta_n)$ and $\tilde{O}_n$, the asymptotic distribution of $n^{1/2} \tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) U_n T_n$ is obtained as follows. We write this matrix in terms of two submatrices:

$$n^{1/2} \tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) U_n B_n S_n$$

$$= (\tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) U_n B_{n,q^S} \overline{Y}_{n,q^S}^{-1}, n^{1/2} \tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) U_n B_{n,p-q^S}). \quad (31.60)$$

Consider the first component on the rhs of (31.60). By definition, the singular value decomposition of $O_n' \tilde{\Omega}_n^{-1/2} D_n U_n$ is $C_n \overline{Y}_n B_n'$ and, as in the proof of the full vector case preceding (25.5), we have $O_n' \tilde{\Omega}_n^{-1/2} D_n U_n B_{n,q^S} \overline{Y}_{n,q^S}^{-1} = C_n q^S$. Hence, we obtain

$$\tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) U_n B_{n,q^S} \overline{Y}_{n,q^S}^{-1}$$

$$= O_n' \tilde{\Omega}_n^{-1/2} D_n U_n B_{n,q^S} \overline{Y}_{n,q^S}^{-1} + n^{1/2} (\tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) - O_n' \tilde{\Omega}_n^{-1/2} D_n) U_n B_{n,q^S} (n^{1/2} \overline{Y}_{n,q^S})^{-1}$$

$$= C_n q^S + o_p(1)$$

$$\rightarrow P \overline{S}_{h,q^S}^S := h_{3,q^S} \in R^{(k-b) \times q^S}, \quad (31.61)$$

where the second equality uses $n^{1/2} (\tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) - O_n' \tilde{\Omega}_n^{-1/2} D_n) = O_p(1)$ and $n^{1/2} \tau_{jn} \rightarrow \infty$ for all $j \leq q^S$ (by the definition of $q^S$ in (31.16)). The convergence in (31.61) holds by (31.14) and (31.15), and the last equality in (31.61) holds by definition. To see that the $O_p(1)$ result holds, we write

$$n^{1/2} (\tilde{O}_n^{-1/2}(\beta_n) \tilde{D}_n(\beta_n) - O_n' \tilde{\Omega}_n^{-1/2} E_n G_i)$$

$$= \tilde{O}_n' \tilde{\Omega}_n^{-1/2}(\beta_n)n^{1/2} (\tilde{D}_n(\beta_n) - E_n G_i) + \tilde{O}_n' n^{1/2} (\tilde{\Omega}_n^{-1/2}(\beta_n) - \Omega_n^{-1/2}) E_n G_i$$

$$+ n^{1/2} (\tilde{O}_n' - O_n') \Omega_n^{-1/2} E_n G_i. \quad (31.62)$$

The $O_p(1)$ result then holds by (31.52), (31.56), and (31.59), $O_n = O(1)$, $\Omega_n^{-1/2} = O(1)$, and $D_n = O(1)$.

Next, consider with the second component on the rhs of (31.60). As in (25.6) and (25.7), we
have
\[ n^{1/2}O_n^{-1/2}D_n B_{n,p-q^s} \to h_3 h_{1,p-q^s}^2. \]  
(31.63)

By (31.52), (31.56), and (31.59), we have

\[ n^{1/2}(\bar{O}_n^{-1/2}(\bar{\beta}_n)\hat{D}_n(\bar{\beta}_n) - O_n^{-1/2}D_n) \]
\[ = n^{1/2}(\bar{O}_n - O_n)^{-1/2}(\bar{\beta}_n)\hat{D}_n(\bar{\beta}_n) + O_n^{-1/2}(\bar{O}_n^{-1/2}(\bar{\beta}_n) - \Omega_n^{-1/2})\hat{D}_n(\bar{\beta}_n) \]
\[ + O_n^{-1/2}(\hat{D}_n(\bar{\beta}_n) - D_n) \]
\[ \to_d \chi_n := \text{vec}_{h^{-1/2}}(\bar{D}_h \text{vec}(\bar{z}_h^S)')h_{5,g}^{-1/2}h_4 + O(h_{5,g}^{-1/2}h_{4,5})'\text{vec}_{h^{-1/2}}(\bar{z}_h^S)h_4 + O(h_{5,g}^{-1/2}h_{4,5})'h_{5,g}^{-1/2}\bar{D}_h. \]  
(31.64)

Using (31.63) and (31.64), we obtain
\[ n^{1/2}O_n^{-1/2}D_n B_{n,p-q^s} \]
\[ = n^{1/2}O_n^{-1/2}D_n U_n B_{n,p-q^s} + n^{1/2}(\bar{O}_n^{-1/2}(\bar{\beta}_n)\hat{D}_n(\bar{\beta}_n) - O_n^{-1/2}D_n) U_n B_{n,p-q^s} \]
\[ \to_d \Xi_{h,p-q^s} := h_3 h_{1,p-q^s}^2 + \chi_n h_8 h_{2,p-q^s} \in R^{(k-b)\times(p-q^s)}, \]  
(31.65)

where \( B_{n,p-q^s} \to h_{2,p-q^s} \), \( U_n \to h_8 \), and \( U_n = U_1(U_2 \to U_1(h_8) =: h_8 \), using the definitions in (16.4), (16.5), and (16.24). Combining (31.60), (31.61), and (31.65) gives the desired asymptotic result because \( \Xi_{h,p} := (\Xi_{h,p}^{h,q^s}, \Xi_{h,p-q^s}) \) by (31.22).

We have \( (\bar{\beta}_n, \bar{D}_h, \bar{z}_h^S, \bar{\nu}_h^S, \bar{\Xi}_h^S) \) is independent of \( \bar{y}_h^S \) because \( \bar{\Xi}_h^S \) is a nonrandom function of \( h \) and \( (\bar{D}_h, \bar{z}_h^S, \bar{\nu}_h^S) \), see (31.22), and \( (\bar{\beta}_n, \bar{D}_h, \bar{z}_h^S, \bar{\nu}_h^S) \) is independent of \( \bar{y}_h^S \) by Lemma 31.5(c). \( \square \)

**Proof of Lemma 31.5(e).** The proofs of parts (a)-(d) of the lemma go through when \( n \) is replaced by \( w_n \). \( \square \)

### 31.3 Proof of Theorem 13.1

The proof of Theorem 13.1 is a combination of the following lemma and the correct asymptotic size results for the subvector AR and CQLR tests given in Theorem 9.1.

In the following lemma, \( \theta_{0n} \) is the true value that may vary with \( n \). For notational simplicity, we suppress the dependence of various quantities on \( \theta_{0n} \).

**Lemma 31.10** Suppose Assumption gB holds. Then, for any sequence \( \{(F_n, \beta_n^*, \theta_{0n}) \in \mathcal{F}_{\Theta,AR}^{S,SR} : n \geq 1\}, \) (a) \( \tilde{r}_n(\tilde{\beta}_n) = r_{F_n}(\tilde{\beta}_n) = r_{F_n}(\beta_n^*) \) wp→1, (b) \( \text{col}(A_n(\tilde{\beta}_n)) = \text{col}(A_{F_n}(\tilde{\beta}_n)) = \text{col}(A_{F_n}(\beta_n^*)) \) wp→1, and (c) given the first-stage estimator \( \tilde{\beta}_n \), the statistics \( S-RAR_n(\tilde{\beta}_n), S-RQLR_n(\tilde{\beta}_n), \)
\( \chi^2_{r_n(\beta_n)} \cdot 1 - \alpha, c_{r_n(\beta_n), p}(n^{1/2} \hat{\beta}_n - \beta_n), J_n(\hat{\beta}_n) \cdot 1 - \alpha \) are invariant \( \text{wp} \rightarrow 1 \) to the replacement of \( \hat{\beta}_n(\beta_n) \) and \( \hat{\beta}_n(\beta_n)' \) by \( F_n(\beta_n) \) and \( \Pi_{1F_n}^{-1/2}(\beta_n)A_F(\beta_n)' \), respectively.

**Proof of Lemma 31.10**

First, we establish part (a). For any \( \beta \in B(\beta_n, \varepsilon) \),

\[
\lambda \in N(\Omega(\beta_n)) \implies \lambda \in \cap_{\beta \in B(\beta_n, \varepsilon)} N(\Omega(\beta_n))
\]

\[
\implies \sup_{\beta \in B(\beta_n, \varepsilon)} \lambda' \Omega(\beta_n) \lambda = 0 \implies \sup_{\beta \in B(\beta_n, \varepsilon)} \text{Var}(\lambda' g_i(\beta)) = 0
\]

\[
\implies \sup_{\beta \in B(\beta_n, \varepsilon)} |\lambda' g_i(\beta) - E(\lambda' g_i(\beta))| = 0 \text{ a.s.}[F_n]
\]

\[
\implies \sup_{\beta \in B(\beta_n, \varepsilon)} \lambda' \hat{\Omega}(\beta_n) \lambda = 0 \text{ a.s.}[F_n] \implies \forall \beta \in B(\beta_n, \varepsilon), \hat{\Omega}(\beta_n) \lambda = 0 \text{ a.s.}[F_n]
\]

\[
\implies \lambda \in \cap_{\beta \in B(\beta_n, \varepsilon)} N(\hat{\Omega}(\beta_n)) \text{ a.s.}[F_n], \quad (31.66)
\]

where the first implication holds by condition (iv) of \( F_{AR,2}^{S,SR} \). From the proof of Lemma 31.5, under sequences \( \{(F_n, \beta_n, \theta_n) \in F_{AR,2}^{S,SR}: n \geq 1\} \), we have that \( \beta_n - \beta_n \rightarrow_0 \). Thus, \( \text{wp} \rightarrow 1 \) it follows that \( \beta_n \in B(\beta_n, \varepsilon) \). Thus, from (31.66), \( N(\Omega(\beta_n)) \subset N(\hat{\Omega}(\beta_n)) \) \( \text{wp} \rightarrow 1 \) and \( \hat{\beta}_n(\beta_n) \leq r_F(\beta_n) \) \( \text{wp} \rightarrow 1 \).

Next we prove \( \hat{\beta}_n(\beta_n) \geq r_F(\beta_n) \) \( \text{wp} \rightarrow 1 \). By considering subsequences, it suffices to consider the case where \( r_F(\beta_n) = r \) for all \( n \geq 1 \) for some \( r \in \{0, 1, ..., k\} \). We have

\[
\hat{\beta}_n(\beta_n) = r k(\hat{\Omega}(\beta_n)) \geq r k(\Pi_{1F_n}^{-1/2}(\beta_n)A_F(\beta_n)' \hat{\Omega}(\beta_n)A_F(\beta_n)\Pi_{1F_n}^{-1/2}(\beta_n)) \quad (31.67)
\]

because \( \hat{\Omega}(\beta_n) \) is \( k \times k \), the matrix \( A_F(\beta_n)\Pi_{1F_n}^{-1/2}(\beta_n) \) is \( k \times r \) \( \text{wp} \rightarrow 1 \) by condition (iv) of \( F_{AR,2}^{S,SR} \) and consistency of \( \hat{\beta}_n \), and wlog \( 1 \leq r \leq k \). (If \( r = 0 \), then the desired inequality \( \hat{\beta}_n(\beta_n) \geq 0 = r_F(\beta_n) \) holds trivially \( \text{wp} \rightarrow 1 \), where the equality holds by condition (iv) of \( F_{AR,2}^{S,SR} \) and consistency of \( \beta_n \).)

From condition (iv) of \( F_{AR,2}^{S,SR} \), it follows that \( A_F(\beta) = A_F(\beta_n) \) and therefore \( A_F(\beta) \) does not depend on \( \beta \) for all \( \beta \in B(\beta_n, \varepsilon) \). For \( \beta \in B(\beta_n, \varepsilon) \), we therefore write \( A_F(\beta) \) for \( A_F(\beta) \) to simplify notation. Furthermore,

\[
\Pi_{1F_n}^{-1/2}(\beta)A_F(\beta)A_F(\beta)\Pi_{1F_n}^{-1/2}(\beta)
\]

\[
= n^{-1} \sum_{i=1}^{n} \Pi_{1F_n}^{-1/2}(\beta)A_F(\beta)g_i(\beta) - E(\lambda' g_i(\beta))g_i(\beta) - E(\lambda' g_i(\beta))' A_F(\beta)\Pi_{1F_n}^{-1/2}(\beta) - \left[ n^{-1} \sum_{i=1}^{n} \Pi_{1F_n}^{-1/2}(\beta)A_F(\beta)g_i(\beta) - E(\lambda' g_i(\beta)) \right] \left[ n^{-1} \sum_{i=1}^{n} (g_i(\beta) - E(\lambda' g_i(\beta))' A_F(\beta)\Pi_{1F_n}^{-1/2}(\beta) \right].
\]

146
By construction and using condition (iv) of \( \mathcal{F}_{AR,2}^{S,SR} \), we have, for all \( \beta \in B(\beta^*_n, \varepsilon) \),

\[
E_F \Pi^{-1/2}_{\hat{I}F_n}(\beta) \hat{A}_{F_n}(\beta) = I_r.
\]

By the uniform moment bound in \( \mathcal{F}_{AR,2}^{S,SR} \), namely, \( E_F \sup_{\beta \in B(\beta^*, \varepsilon)} \| \Pi^{-1/2}_{\hat{I}F_n}(\beta) A_F(\beta) \| ^2 \leq M \) and continuity of \( (g_1(\beta) - E_F g_1(\beta))' A_F \Pi^{-1/2}_{\hat{I}F_n}(\beta) \) as a function of \( \beta \), it follows from a uniform weak law of large numbers for \( L^{1+\gamma/2} \)-bounded i.i.d. random variables, it follows from a uniform weak law of large numbers for \( L^{1+\gamma/2} \)-bounded i.i.d. random variables, for \( \gamma > 0 \) that the expressions in the second and third lines of (31.68) converge in probability to \( I_r \) and \( 0^{r \times r} \), respectively, uniformly over \( \beta \in B(\beta^*, \varepsilon) \). This implies that

\[
\Pi^{-1/2}_{\hat{I}F_n}(\beta_n) A_{F_n}(\beta_n) \hat{\Omega}_n(\beta_n) A_{F_n}(\beta_n) \Pi^{-1/2}_{\hat{I}F_n}(\beta_n) \to_p I_r.
\]

This establishes that \( \hat{r}_n(\beta_n) \geq r \) wp→1 and therefore \( \hat{r}_n(\beta_n) = r \) and \( N(\Omega_{F_n}(\beta_n)) = N(\hat{\Omega}_n(\beta_n)) \) wp→1, which proves (a). In turn, the latter implies that \( \text{col}(A_{F_n}(\beta_n)) = \text{col}(\hat{A}_n(\beta_n)) \) wp→1, which also proves part (b).

To prove part (c), it suffices to consider the case where \( r \geq 1 \) because the test statistics and their critical values are all equal to zero by definition when \( \hat{r}_n(\beta_n) = 0 \) and \( \hat{r}_n(\beta_n) = 0 \) wp→1 when \( r = 0 \) by part (a). Part (b) of the Lemma implies that there exists a random \( r \times r \) nonsingular matrix \( \hat{M}_n \) such that

\[
\hat{A}_n(\beta_n) = A_{F_n}(\beta_n^*) \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) \hat{M}_n \to 1,
\]

because \( \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) \) is nonsingular (since by its definition it is a diagonal matrix with the positive eigenvalues of \( \Omega_{F_n}(\beta_n^*) \) on its diagonal.) Equation (31.69) and \( \hat{r}_n(\beta_n) = r \) wp→1 imply that the statistics \( SR-AR_n^S(\beta_n^*) \), \( SR-QLR_n^S(\beta_n^*) \), \( c_{\hat{r}_n(\beta_n), 1-\alpha} \), \( \hat{\tau}_n(\beta_n) = r \), \( \tau_n(\beta_n) = r \), are invariant wp→1 to the replacement of \( \hat{r}_n(\beta_n) \) and \( \hat{A}_n(\beta_n) \) by \( r \) and \( A_{F_n}(\beta_n^*) \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) \hat{M}_n \), respectively. Now we apply the invariance results of Lemma (31.2) with \( (k, g_1(\beta), G_1(\beta)) \) replaced by \( (r, \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) A_{F_n}(\beta_n^*) g_1(\beta), \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) A_{F_n}(\beta_n^*) G_1(\beta)) \) and with \( M \) equal to \( \hat{M}_n \). These results imply that the previous four statistics when based on \( r \) and \( \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) A_{F_n}(\beta_n^*) g_1(\beta) \) are invariant to the multiplication of the moments \( \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) A_{F_n}(\beta_n^*) g_1(\beta) \) by the nonsingular matrix \( \hat{M}_n \). Thus, the statistics, defined as in Section 5.2, are invariant wp→1 to the replacement of \( \hat{r}_n(\beta_n) \) and \( \hat{A}_n(\beta_n) \) by \( r \) and \( \Pi^{-1/2}_{\hat{I}F_n}(\beta_n^*) A_{F_n}(\beta_n^*) \), respectively, which proves part (c).
31.4 Proof of Theorem 9.2

Proof of Theorem 9.2 By Lemma 31.10 (a) and (b) and \( \mathcal{F}^S \subseteq \mathcal{F}_{AR}^{SR} \) (because \( \mathcal{F}^S \) imposes \( \lambda_{\lim}(E_F g t g_t') \geq \delta \), where \( \mathcal{F}_{AR}^{SR} \) is defined in (9.16)), we have \( \tilde{r}_n(\beta_n) = r_{F_n}(\beta_n) = r_{F_n}(\beta_n) \) and \( \text{col}(\tilde{A}_n(\beta_n)) = \text{col}(A_{F_n}(\beta_n)) = \text{col}(A_{F_n}(\beta_n^*)) \) wp\( \rightarrow \)1. Also, given \( \lambda_{\lim}(E_F g_t g_t') \geq \delta \), it follows that the orthogonal matrix \( A_{F_n}(\beta_n^*) \) is in \( R^{k \times k} \). Given that the statistics \( QLR_n^S(\beta_n) \) and \( c_{k,p}(n^{1/2} \tilde{D}_n^*(\beta_n), \tilde{J}_n(\beta_n), 1-\alpha) \) are invariant to nonsingular transformations by Lemma 31.2, the definition of the subvector SR test in (13.2), combined with the previous two statements imply that \( SR-QLR_n^S(\theta_0, \beta_{\tilde{A}_n}) = QLR_n^S(\tilde{\eta}) + o_p(1) \). Because \( \tilde{r}_n(\beta_n) = k \) wp\( \rightarrow \)1, it follows that 

\[
 c_{k,p}(n^{1/2} \tilde{D}_n^*(\theta_0, \beta_{\tilde{A}_n}), \tilde{J}_n(\theta_0, \beta_{\tilde{A}_n}), 1-\alpha) = c_{k,p}(n^{1/2} \tilde{D}_n^*(\tilde{\eta}), \tilde{J}_n(\tilde{\eta}), 1-\alpha) \text{ wp\( \rightarrow \)1,}
\]

where the latter critical value is the one for the subvector CQLR test without singularity robustness, see (9.12). This proves the first equalities in parts (a) and (b).

We now proceed as in the proof of Theorem 7.1. We replace \( \tilde{W}_n, W_{F_n}, \tilde{\tilde{O}}_n^{-1/2} \tilde{\tilde{g}}_n, \) and \( \tilde{D}_n \in R^{k \times p} \) by the corresponding quantities \( I_k, I_k, \tilde{\tilde{O}}_{F_n} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}), \tilde{\tilde{g}}_n(\tilde{\tilde{\eta}}), \) and \( \tilde{\tilde{O}}_{F_n} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{D}}_n(\tilde{\tilde{\eta}})) \in R^{(k-b) \times p} \), respectively. Note that \( q^S = p \) under \( \{ \lambda_{n,h,t} \colon n \geq 1 \} \). The analogue to (28.2) with \( q^S = p \) therefore states that

\[
\tilde{r}_{(p+1)n}^+ = n \tilde{g}_n'(\tilde{\tilde{\eta}}) \tilde{\tilde{O}}_n^{-1/2} \tilde{\tilde{O}}_{F_n} h_{3,k-p} h_{3,k-p} \tilde{\tilde{O}}_{F_n} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) \tilde{\tilde{g}}_n(\tilde{\tilde{\eta}}) + o_p(1).
\]

In addition, the analogue to (28.3) with \( q^S = p \) states that

\[
QLR_{WU,n}^S = n \tilde{g}_n'(\tilde{\tilde{\eta}}) \tilde{\tilde{O}}_n^{-1/2} \tilde{\tilde{O}}_{F_n} h_{3,p}. h_{3,p} \tilde{\tilde{O}}_{F_n} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) \tilde{\tilde{g}}_n(\tilde{\tilde{\eta}}) + o_p(1),
\]

where \( QLR_{WU,n}^S := AR_{n}^{S}(\tilde{\tilde{\eta}}) - \lambda_{\lim}(n Q_{WU,n}^S) \) is defined below Proposition 31.6 and equals \( QLR_{n}^{S}(\tilde{\tilde{\eta}}) \) when \( \tilde{\tilde{U}}_n \) is taken to be \( \tilde{\tilde{L}}_n^{1/2}(\tilde{\tilde{\eta}}) \). Equation (31.61) implies that \( h_{3,p} = \tilde{\tilde{O}}_{F_n} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) \tilde{\tilde{D}}_n(\tilde{\tilde{\eta}}) U_n B_{n,p} \tilde{\tilde{Y}}_{n,p}^{-1} + o_p(1) \). Because \( U_n B_{n,p} \tilde{\tilde{Y}}_{n,p}^{-1} \) is an invertible matrix, it follows that \( P_{h_{3,p}} = P_{\tilde{\tilde{O}}_{F_n}} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) \tilde{\tilde{D}}_n(\tilde{\tilde{\eta}}) + o_p(1) \). Therefore, using \( h_{3,p} h_{3,p} = I_p \), it follows that

\[
QLR_{WU,n}^S = n \tilde{g}_n'(\tilde{\tilde{\eta}}) \tilde{\tilde{O}}_n^{-1/2} \tilde{\tilde{O}}_{F_n} P_{\tilde{\tilde{O}}_{F_n}} \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) \tilde{\tilde{D}}_n(\tilde{\tilde{\eta}}) + o_p(1).
\]

By (31.48), \( \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) n^{1/2} \tilde{g}_n(\tilde{\tilde{\eta}}) = M_{h_{5,g}}^{-1/2} n^{1/2} \tilde{g}_n(\theta_0, \beta_n^*) + o_p(1) \), where \( h_{5,g} = h_{5,g}^{-1/2} h_{4,\beta} \). Also, \( \tilde{\tilde{O}}_{F_n} = O_{J_h} + o_p(1) \) and \( \tilde{\tilde{O}}_n^{-1/2}(\tilde{\tilde{\eta}}) \tilde{\tilde{D}}_n(\tilde{\tilde{\eta}}) = J_{\theta h} + o_p(1) \), where \( J_{\theta h} := h_{5,g}^{-1/2} h_{4} \) and \( J_{\theta h} \) has full column rank \( p \). Thus, we obtain

\[
QLR_n^S(\tilde{\tilde{\eta}}) = n^{1/2} \tilde{g}_n(\theta_0, \beta_n^*) h_{5,g}^{-1/2} M_{h_{5,g}} O_{J_h} P_{O_{J_h}} J_{\theta h} O_{J_h}' M_{h_{5,g}} h_{5,g}^{-1/2} n^{1/2} \tilde{g}_n(\theta_0, \beta_n^*) + o_p(1)
\]

\[
= n^{1/2} \tilde{g}_n(\theta_0, \beta_n^*) h_{5,g}^{-1/2} P_{M_{h_{5,g}} J_{\theta h}} h_{5,g}^{-1/2} n^{1/2} \tilde{g}_n(\theta_0, \beta_n^*) + o_p(1),
\]

(31.73)
where the second equality uses $O(J_h)O(J_h)' = M_{J_h} = M'_{J_h} M_{J_h}$.

From the above, it also follows that

$$LM_n^S = n^{1/2} \tilde{g}_n(\theta_0, \beta_n^*) h_{5,g}^{-1/2} (M_{J_h} P_{[J_{\theta h} : J_h]} M_{J_h}) h_{5,g}^{-1/2} \tilde{g}_n(\theta_0, \beta_n^*) + o_p(1)$$

(31.74)

using $h_{5,g}^{-1/2} \tilde{G}_{\eta n}(\tilde{n}) \rightarrow_p [J_{\theta h} : J_h] := [h_{5,g}^{-1/2} h_4 : h_{5,g}^{-1/2} h_4, \beta]$ and $[J_{\theta h} : J_h]$ has full column rank $p + b$.

Next, we have

$$M_{J_h} P_{[J_{\theta h} : J_h]} M_{J_h} = M_{J_h} P_{[M_{J_h}, J_{\theta h} : J_h]} M_{J_h} = M_{J_h} \left( P_{M_{J_h} J_{\theta h}} + P_{J_h} \right) M_{J_h} = P_{M_{J_h} J_{\theta h}};$$

(31.75)

where the first equality holds because $[J_{\theta h} : J_h]$ and $[M_{J_h}, J_{\theta h} : J_h]$ span the same space, the second equality holds because $M_{J_h} J_{\theta h}$ and $J_h$ are orthogonal, and the last equality holds because $P_{J_h} M_{J_h} = 0^{k \times k}$ and $P_{M_{J_h} J_{\theta h}} M_{J_h} = P_{M_{J_h} J_{\theta h}}$. Equations (31.73)-(31.75) combine to show that $QLR_n^S(\tilde{n}) = LM_n^S + o_p(1)$, which establishes the second equality of part (a).

By (31.31), $c_{k,p}(n^{1/2} \tilde{D}_n(\tilde{n}), \tilde{J}_n(\tilde{n}), 1 - \alpha) + o_p(1) \rightarrow_p c_{k-b,p,q}(h'_3, k-b-q, \Delta_{h,p-q}^S, 1 - \alpha)$, where $c_{k-b,p,q}(\cdot, 1 - \alpha)$ is defined in (31.19) (and uses the notation in (27.12)). In the present case, $q^S = p$, which implies that $\Delta_{h,p-q}^S$ has no columns, $ACLE_{k,p,q}(\tau^c) = Z_1 Z_1 \sim \chi_p^2$, and $c_{k,p,q}(h'_3, k-b-q, \Delta_{h,p-q}^S \times \Delta_{h,p-q}^S, 1 - \alpha)$ equals the $1 - \alpha$ quantile of the $\chi_p^2$ distribution. Hence, the convergence result in part (b) holds. □
